THE JOURNAL OF THE BOARD OF AGRICULTURE

Vol. XXV. No. 1.

APRIL, 1918.

BRACKEN AS A SOURCE OF POTASH.

Professor R. A. BERRY.

West of Scotland Agricultural College, Glasgow.

G. W. ROBINSON, M.A.

University College, Bangor.

E. J. RUSSELL, O.B.E., D.Sc., F.R.S.,

Director of the Rothamsted Experimental Station.

CONSIDERABLE attention has been directed to the possibility of extracting potash from bracken, and it has been urged that the operation would have the double advantage of increasing the supplies of potash, and of eradicating bracken from land where it is not wanted.

A number of analyses have recently been made in England, Scotland and Wales, which throw important light on the matter and indicate the limitations to which the proposal is subject.

It has been clearly shown that the amount of potash in bracken depends on the stage of growth of the plant. In the early stages potash is the predominating constituent of the ash of the leaves and stems. If it were practicable to collect only the young shoots and burn them, a tolerably pure potassium salt could be obtained without difficulty. As the plant grows bigger it goes on taking up more potash from the soil, but it takes up increasing amounts of other things as well, so that the percentage of potash in the ash falls off. Thus the ash of the young shoots collected in May or early June contains as much as 50 to 56 per cent. of potash (reckoned as K_2O), but this proportion steadily falls off as the plant grows older, till in the full-grown plant the amount of potash in the ash may be below 30 per cent. As, however, the plant is growing all the time, its total content of potash rises till

growth is finished, in spite of this fall in percentage; thus, while the young shoots may yield only 20 lb. of potash per acre the old ones may give 200 lb. or more. When the plant dies and shrivels, however, the potash becomes lost; some of it may go back to the root, and some is washed away by the rain. The loss continues so long as the bracken is exposed to the weather, and finally bracken that has lain out all through the winter becomes very poor in potash, and may contain only 2 per cent.

Thus, there are three general rules governing the amount of potash obtainable from the ash of bracken:—

- 1.—Young bracken yields the purest ash, more than half being pure potash (K_2O). Unfortunately, it does not yield much per acre.
- 2.—Fully-grown bracken yields a less pure ash, containing large quantities of other substances besides potash—

TABLE I.—Percentage of total Potash (K_2O) soluble in Hydrochloric Acid in the Ash of Bracken at various Stages of the Plant Growth.

* Details of the Localities and Soils from which samples were taken :

College Farm, Aber, near Bangor.—Hill pasture lying about 800 ft. above sea level. Soil, a shaley loam. This type of soil generally contains from 0.7 to 0.8 per cent. of K_2O soluble in strong HCl. Samples were taken on 1st June, 1st July, and 25th July. Samples were also examined of the stems and the leaves respectively of the withered bracken taken from the hill in November.

Maes Mynan, Caerwys.—Rough hill pasture on the sides of the Alyn valley. Soil, a glacial sand. These glacial sands contain 0.3 to 0.45 per cent. of K_2O soluble in strong HCl.

Gors Wen, nr. Conway.—Conway valley. Loam over shale similar to the Aber soil.

Bodafon, nr. Moelfre, Anglesey.—Soil, mixed drift, old Red Sandstone and Schist origin. Such soils contain from 0.45 to 0.5 per cent. of K_2O soluble in strong HCl.

Ty Engan, Sarn, Pwllhelis.—Thin, sandy soil from adjoining field, 0.41 per cent.

only about one-third is potash. It yields so much more per acre, however, that the total quantity of potash per plant and per acre is greater than in the case of the young plant.

- 3.—Dried bracken rapidly loses its potash on exposure to the weather, till finally bracken left out all the winter may on burning yield an ash containing only 2 per cent. of pure potash.

Determinations of Potash in 1916.—During the season of 1916 a number of determinations were made of the amounts of potash in bracken ash at the Rothamsted Experimental Station, the Glasgow and West of Scotland Agricultural College, the Agricultural Department of the University College of North Wales, Bangor, and the Fruit and Cider Institute at Long Ashton, Bristol. These show in the early stages of growth considerable, indeed remarkable, similarity in potash content. The results are given in Table I.

Long Ashton (Bristol).

Samples Cut.	Dry Matter. Per cent.	Ash in Dry Matter. Per cent.	Potash in Ash. Per cent.	Potash in dry Matter. Per cent.
May 29th-31st (fronds 6 in. to 8 in. high) ..	17.13	7.02	53.71	3.77
July 1st	—	5.15	44.94	2.32
August 1st	—	6.23	37.12	2.32
September 6th	—	7.14	33.12	2.37

(May samples analysed by C. T. Gimingham; later samples analysed at Rothamsted.)

In this Table the percentages given are those extracted by hydrochloric acid. Almost all of the potash, however, is soluble in water; at Bristol 99 per cent. is so soluble, in Ayrshire over 90 per cent., and in the Welsh experiments the proportion varies from 50 per cent. in the exceptional case of Maes Mynan and 80 per cent. at Ty Engan. to the more usual 95 per cent. at Aber and Gors Wen.

The amounts of total potash in the bracken ash at Dundonald Glen, Cleveance and Harpenden Common are very similar; in all cases the soil is mainly mineral and without peat. Dundonald Glen has a deep fertile soil, Cleveance a shallow soil in an exposed position on the side of a hill. The analyses of the Harpenden Common samples were made at Rothamsted; the Common soil is mainly gravel and clay. The bracken on

Shewalton Moss, which has 6 or 7 ft. of peat, begins in May with 54 per cent. of potash like the others, but other constituents are taken up so quickly that the proportion falls more rapidly. The North Wales soils show a similar rapid drop.

The North Wales results indicate that bracken from sandy soil contains less potash in its ash than bracken from loamy soils; Maes Mynan and Ty Engan both being sands, containing 0.3 to 0.45 per cent. of total potash,* while Gors Wen, Aber and Bodafon are loams, the first containing 0.7 to 0.8 per cent. of total potash, while a field adjacent to the last contains 0.6 per cent. The result may be associated with the lower content of potash in sandy soils. Maes Mynan gave by far the most luxuriant crop, but the charred residue showed the abnormal property of bursting into flames when it was heated.

Assuming that the potash is worth 10s. per unit—an estimate possibly on the low side, seeing that 90 per cent. is soluble in water—then the following would be the value of 1 ton of bracken ash collected at various times:—

At first sight these figures seem very attractive, but, as anyone who tries it soon realises, the collection of a ton of bracken ash in a dry state is no simple matter. A clearer notion of the value of bracken as a source of potash is obtained by estimating the quantity of potash obtained from an acre of ground.

The Quantity of Potash obtainable per Acre.—None of the measurements extends over a whole acre, and an estimate can only be obtained by multiplying up the measurements made on

* *i.e.*, Potash (K_2O) soluble in hydrochloric acid.

a few square yards. The figures are approximations only, and are to be taken simply as numbers for guidance.

The quantity of ash obtained in lb. per acre is given in Table II., from which it appears that 4 to 10 acres of bracken have to be cut to yield 1 ton of bracken ash. The experimenters agree that 7 to 10 acres would be typical of considerable areas of bracken in the country.

TABLE II.—*Approximate Quantity of Ash in lb. per Acre obtained by burning Bracken.*

Ty Egan	40	52

From this table it is evident that much less potash is obtainable from an acre of bracken on Harpenden Common than in Ayrshire, but even in Ayrshire the amount is very variable. If cut in July or August, Dundonald Glen and Shewalton Moss would yield $2-2\frac{1}{2}$ cwt. of K_2O per acre. Assuming as before that the potash is worth 10s. per unit the value of the ash obtainable from an acre of ground would be £5 at Dundonald and Shewalton, £2 10s. at Cleavance, and 27s. 6d. at Harpenden Common, provided always, of course, that the whole of the ash is collected and kept dry throughout. The bulk of the potash is in the form of sulphate, chloride and carbonate—salts which are easily soluble in water. Rain, therefore, has a disastrous effect on the ash, reducing the amount of potash. If the ash is not collected at once, or if it is allowed to become wet or to be washed out by rain, it loses considerably in value.

Another estimate has been published by the Scotch Board of Agriculture.* One acre of bracken is estimated to yield 2 cwt. of ash when growth is sparse, and up to 5 cwt. when growth is thick and vigorous. The potash content of the ash varies between 30 and 40 per cent.; the value of the ash would run from £18 to £25 per ton when potash is 12s. 6d. per unit, or £14 8s. to £20 when the unit price is 10s. as we have previously assumed. The amount of potash obtained per acre is estimated to vary from about 70 to about 220 lb.

The Amount of Ash obtainable from a Ton of Bracken.—Table IV. shows the amount of dry matter and of ash in the bracken as collected. The dry matter in the bracken as it reaches the

laboratory varies from about 8 per cent. in the early stages to nearly 40 per cent. at full growth, and more than 70 per cent. in the dry shrivelled leaves in autumn.

Factors Determining the Amount of Potash Yielded per Acre.—The first point to notice in the tables just given is that the purest ash in no case gives the highest yield of potash per acre; the high grade 54 or 56 per cent. ash yielded by the young shoots, which has appealed very much to some writers in the Press, is so small in amount that it only gives 9 or 10 lb. per acre, a quantity wholly inadequate. Further, directly the bracken begins to die it suffers very considerable losses. Bracken cut during late autumn or winter, the time when it is usually gathered by farmers, contains very little potash. This is the time when labour and wagons can best be spared, but it is not the time to get the best yield of potash. Only during July and August, when the bracken is still green, is any large amount of potash obtainable.

During these months the chief factor determining whether the bracken is worth cutting is its bulk. The difference between Harpenden Common and Ayrshire lies not so much in the difference in potash content, as in the relative luxuriance of growth. In Ayrshire the fronds were 5 to 6 ft. in length—at Harpenden they only came up to a man's knees.

As between different samples of bracken there is a closer similarity than might have been expected in the very early stage of growth, but the relative richness quickly falls off, and more rapidly in some cases than in others. There are not sufficient data to make a general rule, but so far as the evidence goes the falling off appears to be more rapid on sandy or peaty soils than on heavier soils rich in potash; consequently, it is on these heavier soils that the chances of success would be best.

Probable Cost of Collection.—It is difficult to make any estimate of the cost of collection. Cutting would hardly be done at less than 10s. per acre, the turning may cost 5s., and the collecting, burning, etc., 7s. 6d. per acre. The total cost of the ash on the hill or common is thus at least 22s. 6d. per acre; probably 30s. per acre would be nearer the price. We have seen that the potash in the ash may be worth at most 27s. 6d. to £5 if all the ash is saved and none exposed to rain. Where, as often happens, the land is not easily accessible the cost is increased.

Reckoning the values per ton of ash, the cost of collection might be anything up to £12 or £15 per ton, and the value in perfect condition up to £15 or £20. The ideally perfect conditions, of course, can never be fully realised in practice, and in many cases it would be impossible to keep the ash wholly out of the rain; it might well happen that the value of the ash could only just repay the cost. Where bracken grows luxuriantly and the fronds are 6 or 7 ft. long, however, as in Dundonald Glen, besides being closely packed on the ground, then burning appears to be profitable.

Use as Litter.—There is, however, another and better way of using bracken, and that is to cut it for bedding or litter. This plan has the advantage of furnishing not only potash, but also nitrogen and organic matter to the farm. And, moreover, every load of bracken brought in liberates straw for the Army or for feeding live stock. The plan is not always feasible, because the bracken may be too far away from the farm, but where possible it ought to be adopted.

The Amount of Potash in Other Vegetable Products.—André (*Chimie Agricole*) has shown that the potash content of the ash of certain other leaves and twigs varies in the same way as in the case of bracken, being high in the early part of the year and then falling rapidly. The percentages of potash (K_2O) in the ash were, in the cases examined by him:—

		Leaves of <i>Robinia</i> .	Leaves of Cherry Laurel.	Twigs of Walnut Tree.
April	..	—	32·8	—
May	..	30·6	—	—
July	..	19·2	17·8	35·7
September	..	6·6	12·1	16·9
October	..	3·2	11·8	—
November	..	—	—	11·4

The rule is probably general ; Wolff showed many years ago that potato haulm contains about 40 per cent. of potash in its ash in June, about 30 per cent. in July, but only 20 per cent. in August.

All plants contain potash, some more than others. The amount varies according to the conditions of growth and the stage of maturity, but the general results are as follows :—

	Percentage of Potash in Ash.
<i>Certain seed cases, pods and peelings are richest :—</i>	
Green cases of horse chestnut, potato peelings	70—77
Bean pods	60—70
<i>Certain materials rich in starch or sugar come next :—</i>	
Potato tubers, horse chestnuts, acorns, mangold roots, sunflower (whole plant), rhubarb stalks, pears, plums, grapes	55—65
<i>Certain weeds, which unfortunately are not of dense growth, come next :—</i>	
Achillea millefolium, Borago officinalis, Centaurea cyanthus, Chrysanthemum segetum, Cuscuta europæa, Ranunculus Ficaria, Matricaria Chamomilla, Urtica dioica (stems), Stellaria media	45—55
Beans, peas, straw, turnip root	40—45
<i>A large number of plants taken whole and in full green growth contain</i>	30—40
e.g., Clovers, potato haulm, mangold leaves, bracken, twigs and young wood generally, many weeds.	
Hay	25—35
<i>Fully ripe plants contain less :—</i>	
Wheat grain, barley without seed coats, oats without seed coats	30
Barley with seed coats	20
Oats	15
Oat and barley straw	20
Wheat straw	10—15
Older wood	15—25
Seaweeds	15—20
Hop bine (according to degree of withering) ..	1—25
Lichens, mosses, heaths	5—10
Dead wood and other vegetables left exposed } to weather }	Down to 1 or 2

However high the potash content of the green growing plant it falls rapidly when the plant withers and is left exposed to the weather. The general rubbish burnt in the field or garden bonfire yields an ash containing only 10-12 per cent. of potash.

General Conclusions.—Wherever bracken can be used as litter or bedding it should be done ; not only is this a saving of straw but also an enriching of the farm stock of nitrogen, potash and organic matter.

The best time to cut is July or August, which unfortunately is a busy period for the farmer. Bracken suffers serious losses in potash when it is left out exposed to the weather, and the dead bracken carted in the winter months is nothing like as rich in potash as the green August growth.

Bracken that for any reason cannot be utilised for bedding may well be burnt for its ash, provided always that the operation is so carried out that the ash is not exposed to rain at any time. July and August are the best months. The work could hardly be done by farmers, but would need to be undertaken by some outside organisation.

THE FEEDING OF CONCENTRATED FOOD TO DAIRY COWS ON PASTURE.

In their joint statement of policy* with regard to the use of concentrated feeding stuffs for livestock, the Board of Agriculture and the Ministry of Food lay down the rule that during the coming months cows in milk while out at grass should receive no concentrated food before the beginning of August. In some districts this restriction will involve no departure from existing practice, but in many other districts, where it has been customary to give concentrated foods to milch cows throughout the pasture season there will be considerable apprehension as to the effect upon milk supplies of withholding such foods.

The question has been submitted to practical tests in several widely-separated areas during recent years, and the following summary of the results obtained may serve to allay any undue apprehension that may be felt. In each case the experiments have been carried out in areas where it is the common practice to give concentrated food to cows on grass.

Armstrong College Experiment, 1905 (*vide* Offerton Bulletin No. 2).—This experiment covered a period of 12 weeks from 19th June to 12th September, 1905. Two lots of 5 cows each were used; one lot receiving no concentrated food throughout the period, whilst the other lot received for the first 6 weeks a daily allowance per cow of 2 lb. maize, 2 lb. Bombay cotton cake and 2½ lb. straw chaff, these quantities then being

* This *Journal*, February, 1918, p. 1177.

increased for the second 6 weeks to 4 lb., 4 lb. and 3 lb. respectively. Prior to the experiment, when all the cows were fed alike, the two lots gave almost equal milk-yields, viz., 167 and 170 pints per day respectively.

For the two periods of the experiment the average daily milk-yields were as follows :—

		No "Cake."		"Cake."	
		Pints.		Pints.	
Period I. (6 weeks)	..	128·7	..	128·3	
„ II. (6 „)	..	109·2	..	112·9	
Average for 12 weeks		118·9	..	120·6	

Clearly no return in milk was obtained for the concentrated food consumed, although there were indications of an increasing effect in the last few weeks. Periodical analyses of the milk similarly afforded no evidence of any effect upon the quality of the milk. Only in the live-weight of the cows was any effect discernable, and that only small, the cake-fed cows showing an average gain over the whole period of 28 lb. as compared with a decrease of 11 lb. in the other lot.

Armstrong College Experiment, 1906 (*vide* Offerton Bulletin No. 2).—The foregoing experiment was repeated on precisely similar lines during the following summer for a period of 10 weeks (18th June—27th August, 1906). The two lots of cows gave identical milk-yields (151 pints per lot per day) during the preliminary period when treated alike. For the experimental period the average results were as follows :—

		No "Cake."		"Cake."	
		Pints.		Pints.	
Period I. (5 weeks)	..	138·4	..	136·4	
„ II. (5 „)	..	108·7	..	112·4	
Average for 10 weeks		123·6	..	124·4	

Thus again, taking the period as a whole the concentrated food produced no appreciable effect, although it was undoubtedly beginning to tell towards the end. No effect could be traced upon the quality of the milk. The average live-weight decreased slightly in each case, the cake lot curiously showing the larger decrease, viz., 74 lb., as compared with 19 lb.

Wye Experiment, 1908.—In this trial, conducted at the South-Eastern Agricultural College, Wye, two lots of 3 cows each

were compared for the period of 10 weeks, from 11th June to 19th August, 1908. For the first fortnight all the cows were treated alike, receiving no concentrated food. During this period one lot gave per week 660 lb. of milk containing 21.6 lb. of fat, whilst the other lot gave 666 lb. of milk containing 20.4 lb. of fat. Subsequently, the second lot received an allowance, starting with 2 lb. and rising to 4 lb. per cow daily, of a mixture of linseed cake and undecorticated cotton cake.

For the 8 weeks during which this differential feeding was continued the no-cake lot gave on the average per week 576 lb. of milk containing 18.9 lb. of fat, whilst the cake-fed lot gave 567 lb. of milk containing 18.8 lb. of fat. The cake-fed lot had thus slightly the worse record in milk-yield but a small advantage in yield of fat. It is obvious, however, that as regards output the cake-feeding must have been entirely unprofitable. In this experiment no records of live-weight were taken.

Leeds University Experiment, Garforth, 1914.—This experiment was carried out with 2 lots of 6 cows each for the period of 19 weeks from 21st April to 28th August, 1914. For a month prior to the experiment the lots received identical rations, and for this period showed weekly average milk-yields of 863 lb. and 905 lb. respectively. During the experimental period the latter lot received no concentrated food, whereas the former received from 2 lb. to 4 lb. of cake per cow daily throughout. The records for successive short periods of the experiment are summarised below :—

		<i>Average Milk Yield per Lot per Week.</i>		<i>Decrease in Average.</i>	
		<i>Lot A. (Cake).</i>	<i>Lot B. (No Cake).</i>	<i>Lot A.</i>	<i>Lot B.</i>
		lb.	lb.	lb.	lb.
Preliminary period (4 weeks)		863	905	..	—
Experimental period—					
1st 3 weeks	742	815	..	121 90
2nd „	653	730	..	89 85
3rd „	585	658	..	68 72
4th „	532	588	..	53 70
Last 2 weeks	452	481	..	80 107
Average for 19 weeks		603	667	..	260 238

It will be seen that, taking the whole period, the cake-fed cows showed a somewhat greater shrinkage in milk-yield than Lot B. On the other hand the averages for the successive sections of the period showed that after the first 6 weeks the milk-yield of Lot B decreased at a progressively greater rate

than Lot A. This is brought out clearly in the following table, in which the two sets of data have been put upon a strictly comparable basis by taking the average for the preliminary period as 1,000 lb. for each lot, and then adjusting the other averages in proportion :—

		Average Milk Yield.			Decrease in Average.	
		Lot A.	Lot B.		Lot A.	Lot B.
		lb.	lb.		lb.	lb.
Preliminary period	..	1,000	1,000	..	—	—
Experimental period—						
1st 3 weeks	..	860	900	..	140	100
2nd „	..	757	807	..	103	93
3rd „	..	678	727	..	79	80
4th „	..	616	650	..	62	77
Last 2 weeks	..	524	531	..	92	119
Average for 19 weeks	..	699	737	..	301	263

The critical point after which the cake-fed cows began to show more and more to advantage would seem to have been about the ninth week of the experiment, or the middle of July.

No influence of the cake-feeding upon the quality of the milk could be detected. Each lot gained in live-weight, the average gain per cow for the period being 82 lb. for Lot A and 24 lb. for Lot B. The expenditure on cake was clearly not compensated for by this slight improvement.

West of Scotland Experiments, 1912-14 (West of Scotland Agricultural College, Bulletin No. 76).—This is the most extensive series of experiments on the subject yet carried out, and comprises 15 separate comparisons made on seven farms during 3 years. On three farms the test was repeated each year, on two farms for 2 years, and on the remaining two farms 1 year's test only was carried out. The total number of cows included in the tests was 224, the numbers used at each centre being mostly sixteen, divided into two lots.

The experiment proper started about the middle of July in each year and lasted three months (12 weeks), although the daily milk records were continued further until most of the cows were dry. At each centre both lots of cows were treated exactly alike, except that one lot received per cow 2 lb. of concentrated food daily (mixed decorticated cotton and soya cakes) in the first month and 4 lb. of the same in the second and third months.

The results are summarised in the following table :—

Average Monthly Yield of Milk per Centre.
(Lot A—no cake. Lot B—cake fed.)

* Average daily yield per cow.

The detailed returns given in the Report show that the concentrated food consumed on the pastures produced a progressive increase in milk-yield for each month in favour of Lot B at most of the centres. In round figures the increase in favour of each of the cows receiving the extra food amounted on the average to a little under 1 gal. of milk per week in the first month, to a little less than $1\frac{1}{4}$ gal. per week in the second month, and to nearly 2 gal. per week in the third month of the experiment. The increases varied considerably at the different centres and in the different years.

Taking the whole series of experiments the increase in milk-yield due to cake-feeding amounted to 8·7 per cent., of which 1·9 per cent. (say 2 per cent.) is credited to the first month, 2·8 per cent. (say 3 per cent.) to the second month, and 4·0 per cent. to the third month.

No measurable influence upon the fat-content of the milk could be detected, apart from an apparent slight depression in this respect recorded by the cake-fed lot which was most probably simply attributable to the slower decline in milk-yield with advance of lactation.

The cows were not weighed, but, judged by the eye, the condition of the cows in both lots was much the same at each centre at the end of the experiment.

A profit-and-loss account, based upon the value (at the time) of the increased milk yield as compared with the cost of the cake, is given in the Report and shows on the average of all experiments a loss of 10s. 1d. per cow for the 12 weeks. Assessed on these lines a small profit was shown in only one of the fifteen tests, although in a second case the indicated loss was only very small.

If allowance be made for the manurial value of the cake consumed (per Hall & Voelcker's Tables) the above average loss is reduced from 10s. 1d. to 2s. 6d.

After the close of the experiment, when the cows were treated alike, the milk-records for the succeeding month showed a continued advantage in milk-yield for the cows that had been receiving the cake, although the increase for this fourth month was not maintained at the same progressive rate as that of the preceding months. If allowance be made for this extra month in the estimate of profit and loss the apparent loss of 2s. 6d. is converted into an apparent profit of 3s. per cow.

"The weather during the 3 years of the experiment was somewhat exceptional, inasmuch as the total rainfall each year was below the mean, and the deficiency occurred mostly in the late summer and autumn months. It is probable, therefore, that the weather conditions prevailing during the period of the experiment gave rise to effects on the pasture which would be more favourable to the results from the feeding of the cake compared with other years. A distinct scarcity of grass was recorded at several centres where the response was greatest."

General Conclusions from the Various Experiments.—It is rarely in agricultural experimental work that the results obtained in different experiments carried out at such widely-scattered centres are so uniformly concordant as in the experiments dealt with above. They all agree in indicating that, so far as milk production is concerned, the feeding of concentrated food to milch cows on pasture is only required in the later half of the pasturage season, say, from mid-July onwards. In the earlier half of the season, cows receiving concentrated food gave no more milk than others that received none. Even in the later months, when the effect of "cake"-feeding began to show, the results were so modest that there could be no question of much profit, even on the most generous method of assessment. In practically every case the cows paid neither in quantity nor quality of milk nor in improved bodily condition for the concentrated food used. The only other possibility of profit lies in the manuring of the pasture, but any benefit secured in this direction by the cake-feeding must have been dearly bought.

It is not overlooked that the character of the pasture and the nature of the season must considerably affect the requirement for supplementary cake-feeding, but the range of variation of pasture, locality and season in the experiments were

such as to leave little doubt that the conclusions are applicable to any but abnormally bad conditions. They certainly warrant the opinion that during the coming pasture season the average dairy-farmer need have no misgivings in refraining from the use of concentrated feeding stuffs until the pastures get beyond their best, which with a normal season should be towards the end of July in most parts of the country.

BAYNARD'S ESTATE, CRANLEIGH :

AN EXAMPLE OF A WAR COMMITTEE'S EFFORTS TO INCREASE FOOD PRODUCTION.

THIS estate, situate on the Surrey and Sussex borders distant 3 miles from Cranleigh, comprises some 1,362 acres, of which 405 acres were arable, 457 acres pasture, and 500 acres were occupied by woods, buildings, roads, etc.

The estate was purchased by its present owner some 16 years ago ; some 250 acres of the arable land had been allowed to go out of cultivation and were covered with briars, seedling birch trees, rough grass and weeds. The extensive farm buildings were unused and the cottages stood empty ; except for a few horses there was no stock kept, and the land was overrun with game and rabbits, of which the extensive woods held a large stock. The woods mainly served as game cover, though there was some fair timber, but the single trees in the arable land offered considerable difficulties to cultivation. The soil is of a heavy character, subsoil clay and gravel, and in some places is of a brashy nature, while much of it lies very wet.

The attention of the Surrey War Agricultural Executive Committee was called to the estate during the survey of the county which was made in order to discover what extra amount of land could be brought into or restored to cultivation for the production of food in the present national emergency. The owner was unable to comply with the Committee's wishes to bring the arable land again under the plough, and to convert some of the pasture to arable, and the estate was therefore entered upon and possession taken by the Committee, which succeeded after some negotiations in letting the arable and pasture land, together with the vacant buildings, to three neighbouring farmers, Messrs. Johnston, Sadler and Fortune, on certain terms, these farmers agreeing to cultivate the land in accordance with the scheme framed by the Committee

through their Executive Officer, who submitted an estimate of the probable cost—the scheme and the estimate being accepted by the Food Production Department of the Board of Agriculture. The negotiations were commenced in April, 1917, and the approval of the Board was given in July of that year. It was agreed that the tenants should receive a grant of £4 per acre on the 230 acres of derelict land towards the cost of cultivation and should pay an agreed rent—the result of the transaction being that the amounts of the rent received will balance the payments made for bringing the land into cultivation. The valuation on the northern section of the land, comprising 174 acres taken by Mr. A. B. Johnston, amounted to nothing, as the land was derelict. On the southern section, also taken by Mr. A. B. Johnston, no valuation was allowed on 20 acres 3 roods, which had been ploughed and sown with oats in 1915, and was in such a foul state that it was quite unfit to be put under corn. On another part of the northern section, taken by Mr. J. A. Sadler, no valuation was allowed on 14½ acres, although this had been ploughed and sown with oats, for the same reason as mentioned in the case of Mr. Johnston, whilst on another part of the southern section taken over by Mr. R. Fortune no valuation for a similar reason was allowed on a field of 15 acres. All the hay on the estate had been sold to the Government, some being only fit to be used for litter, and there was consequently no hay for the tenants to take over. On the expiration of their tenancies, therefore, they will be entitled to sell the hay they produce at market price. As Surrey valuations are made on the basis of a Michaelmas entry the outgoing tenant would in the ordinary course be entitled to rent and rates from Michaelmas, 1916, on land from which he had not taken any crops or which he had not fed in any way. The neglected state of the whole of the land taken over precluded any claims of this nature being made on any of the incoming tenants, except in the case of ¾ acre put in with potatoes on Mr. Johnston's holding. The foregoing details are given in order to show the state of the land on entry by Messrs. Johnston, Sadler and Fortune. This can also be realised by reference to Fig. 1. The woods of some 400 acres were taken over by the Committee in order to control the rabbits, and leave was given to the owner to enter the woods for the purpose of cutting and removing timber and underwood, on condition that he undertook to pay full and fair compensation to the tenants of the land for any actual damage caused thereby to the property of the tenants. As some of the

FIG. 1.—Land before clearing, showing twenty years' growth of weeds and bushes.

FIG. 2.—Tractor and Plough that have broken up 150 acres in five weeks, later ploughing the second time six acres per day.

FIG. 3.—Oats grown the first year after ploughing, on land which had previously been derelict for fifteen years, now in Mr. Johnston's occupation.

FIG. 4.—Wheat grown in 1916, on land previously derelict.

timber which is marked to be felled is on the edge of the arable land and there are dotted amongst the fields fair timber trees which should be thrown, great care will have to be exercised in felling and removing, as the damage which may be caused to the crops and to the interests of food production cannot be compensated by any money payment to the tenants. It may be mentioned that the sporting rights on the estate were let to Mrs. Naumann. The acreage taken by the three neighbouring farmers and the rents reserved were as follows :—

		<i>A.</i>	<i>r.</i>	<i>sq.</i>	<i>p.</i>	<i>Derelict.</i>	<i>Rent.</i>
Mr. Johnston	..	359	3	36	..	190 acres	.. £137
„ Sadler	..	303	0	14	..	70 „	.. £186
„ Fortune	..	200	0	2	..	100 „	.. £150

These three farmers are all busy men. Mr. Johnston farms 600 acres, Mr. Sadler 371 acres, and Mr. Fortune 350 acres, besides Baynard's holdings. It says much for the energy and business capacity of these gentlemen that they should, at a time when less enterprising men are complaining that they cannot carry on satisfactorily their own holdings and cannot possibly plough up any grass or take on any additional responsibilities, undertake such extensive additions to their businesses, especially when the reason given by the owner and late occupier for putting so much of the land to grass and allowing practically the whole of the remainder to become derelict was that it was the more remunerative plan. Of course when corn was at 25s. per qr. the case was different, but the present prices are counterbalanced to a considerable extent by the increased costs of production, and there is no doubt that the three farmers' enterprise was seasoned with a very considerable amount of patriotic spirit.

At the first visit paid by the writer to Baynard's before the ploughing was finished the state of the derelict land was appalling. Mr. Johnston had purchased two Overtime tractors which he and his brother, who had been released from the Army for the purpose, worked night and day. Mr. Sadler had bought one, whilst Mr. Fortune has had the services of a steam plough and a Government tractor, and excellent work was being done (See Fig. 2). Unfortunately a wet harvest made difficulties, and a succeeding wet spell in the autumn, during which the plough was idle, prevented the complete scheme of cropping with winter corn being carried out. Mr. Johnston, however, got in 144 acres with wheat out of the 174 acres contemplated, Mr. Sadler 40 acres out of 57 contemplated, and Mr. Fortune 35 acres. Some of this land is so heavy and wet that it must be

ploughed early in narrow lands, and the wheat got in by the middle or end of September, so as to get a plant which will stand the winter—if this opportunity be missed, later sowing is most undesirable, and it is best to leave the land ploughed for winter seasoning so as to get in the spring corn at the first opportunity. This plan was followed on such land as it was not found possible to sow earlier in the season, owing to the wet weather. The second visit was paid in November, and the changed character of the landscape was very striking—on most of the newly-sown land the wheat was braiding well; on a part where some years back a plantation existed the plant was thin; the ravages of rabbits were, unfortunately, too evident (this pest is, however, being dealt with energetically) and there was as yet not much evidence of wireworm attack, but the land required consolidating by rolling at a favourable opportunity. Mr. Johnston had dressed a considerable portion of the derelict land with lime, and it was intended that other portions should be chalked, while the whole had been dressed with basic slag, of which 80 tons had been used. Messrs. Fortune and Sadler had also slagged and limed their land. The corn was to be top-dressed in March with sulphate of ammonia where it appeared to be necessary. The seed wheat used by Mr. Johnston is of the Red Standard variety, and was grown by him on a field of 30 acres which he rescued from a derelict state a year previously. Fig 4 shows the crop of seed wheat growing on the land previously derelict. To preserve the crops from the depredations of rabbits a very considerable amount of wire netting would be required, and as this is at the present time almost unprocurable, and the shooting of the rabbits means a tax on the farmer's time, which with the present labour shortage is a serious matter, some damage must result. It has been found a better plan to wire in the plantations as far as possible, and some 10,000 yd. of wire netting, 5,000 yd. of which were taken over in the valuation and 5,000 yd. purchased by the farmers, have now been erected. Mr. Johnston intends to crop the greater part of his land now under wheat with winter oats in 1919, and by so doing he will have made a very substantial addition to the foodstuffs of the country. Mr. Johnston will have his 360 acres cropped as follows for the 1918 harvest: wheat, 144 acres; spring oats, 30 acres; potatoes 25 acres; peas or oats, 45 acres; the rest being rough pasture which has been well slagged.

Mr. Sadler is cropping his 303 acres in 1918 as follows: wheat, 57 acres; barley, 20 acres; oats, 96½ acres; remainder

rough grass. Mr. Sadler threshed a crop of oats which had been grown on 17 acres (part of the land he now has under wheat), and the yield totalled 20 qr., weighing 28 lb. per bush.!

Mr. Fortune's cropping for 1918 of his 200 acres is 35 acres wheat, 25 acres oats or barley, 10 acres swedes; the remaining 130 acres of grass, being well watered, are being brought into good heart by slag and ground lime in order to carry part of his Dairy Shorthorn herd, and so release more of Mr. Fortune's own farm for arable cultivation.

447 acres of corn are thus being added to the food supply, and this with a fair harvest should add some 2,400 qr. of corn to the nation's food supply; in addition the grass land will carry at least twice the head of stock it carried previously, and when it is considered that probably not 100 qr. would have been produced under the old management it must be allowed that the activity of the War Committee and the enterprise and patriotism of these three farmers promise a useful result.

PIG FEEDING IN WAR TIME.

PART III.*

J. FLEMING, Univ. Dipl. Agric., Camb.,

Assistant to the Reader in Agriculture, Cambridge University.

It was decided to fatten the hog pigs from Lots A and B, of which an account was given in the November issue of this *Journal*, which described the feeding and rearing of the pigs down to 3rd October, 1917.

The rations being fed to them at that date were as follows:—

Lot A.		Lot B.	
$\frac{1}{2}$ lb. sharps,	} As slop.	$\frac{1}{2}$ lb. sharps.	} As slop.
$\frac{1}{2}$ „ tail barley meal		$\frac{1}{2}$ „ tail barley meal	
2 „ marrow-stemmed kale.		2 „ marrow-stemmed kale.	
$\frac{1}{2}$ „ palm kernel cake.		$\frac{1}{2}$ „ palm kernel cake.	

Further, the pigs were out on grass day and night.

On 10th October the pigs were weighed, and the hogs, fifteen in number, were separated out and run in an open yard. Their ration was then—

3 lb. marrow-stemmed kale (cut)	} mixed.
1 „ palm kernel cake.	
$\frac{1}{2}$ „ sharps,	} As slop.
$\frac{1}{2}$ „ tail barley meal	
6 „ marrow-stemmed kale (uncut).	

* For Parts I. and II. see this *Journal* for October and November, 1917.

After a few days it was found that the marrow-stemmed kale was not eaten very readily. This was evidently due to it having become tough and stringy, as earlier in the year, when the stems were soft and succulent, the pigs had eaten it with avidity. Cabbage was therefore used to replace it.

About the middle of October the weather became very wet and the yard in which the hogs were running became very dirty; they were therefore put into the fattening pens, and divided up as follows :—

<i>Pen. I.</i>		<i>Pen II.</i>		<i>Pen III.</i>	
Sow 2,	Pig 4, 93 lb.	Sow 2,	Pig 3, 90 lb.	Sow 2,	Pig 1, 78 lb.
" 2	" 7, 73 "	" 3	" 4, 93 "	" 3	" 2, 96 "
" 3	" 3, 94 "	" 3	" 5, 83 "	" 4	" 3, 91 "
" 4	" 8, 88 "	" 4	" 1, 88 "	" 4	" 6, 78 "
" 1	" 4, 89 "	" R.M.	76 "	" 1	" 3, 108 "
<hr/>		<hr/>		<hr/>	
Total ..	437 lb.	Total ..	430 lb.	Total ..	451 lb.
Average	87.4 "	Average	86.0 "	Average	90.2 "

All the pigs from sows 1, 2 and R.M. were Lot A pigs, and all those from sows 3 and 4 were Lot B pigs. Great care was taken to make the three pens as even as possible. As the hogs were not weighed on the day they were put in the pens, the weights given are those taken on 10th October.

Sawdust and wood chips were employed as litter during all the time the hogs were fed, and on them the pigs were kept clean and comfortable.

Owing to difficulties in obtaining supplies, it was found necessary on 19th October to substitute coconut cake for the palm kernel cake; this change was made gradually, and as soon as supplies of the palm kernel cake were available, it was again used.

There were on the farm a supply of " chat " and diseased ware potatoes, unfit for human consumption, and as it was intended to use these throughout the fattening period, a start was made on 1st November by giving the hogs 1½ lb. per head, mixed with their cut cabbage and cake. After two days an additional 1½ lb. were fed to them mixed in the evening slop. No difficulty was experienced in getting the hogs to eat the potatoes.

On 6th November, after an interval of 28 days, the hogs were again weighed, showing a gain for Pen I. of 24.8 lb., for Pen II. of 25.6 lb., and for Pen III. of 25 lb. (See Table I., cols. 1 and 2.)

From this date (6th November) slop was discontinued altogether and was replaced by :

4 lb. potatoes,
 1 " sharps,
 1 " barley (tail) meal,
 in addition to 9 lb. cabbage and 1 lb. coconut cake.

The potatoes, which were fed *raw*, were mixed with the dry sharps and barley meal. Cutting the potatoes in the turnip cutter was found to be impossible, owing to the danger of stones getting in and breaking the knives, so they were roughly chopped. After 14 days, that is on 20th November, the pigs were again weighed.

when Pens I. and II. showed practically the same increase as at the previous weighing, but Pen III. had not done so well. (See Table I., cols. 3 and 4.) So far the hogs had only been on a ration which was a little better than store, but from 20th November their fattening rations were fixed as follows:—

<i>Pens I. and II.</i>		<i>Pen III.</i>	
1 $\frac{1}{2}$ lb.	coconut cake.	1 lb.	coconut cake.
$\frac{1}{2}$ „	sharps.	$\frac{1}{2}$ „	sharps.
$\frac{1}{2}$ „	barley (tail) meal.	$\frac{1}{2}$ „	barley (tail) meal.
12 „	potatoes.	12 „	potatoes.
4 „	cabbage.	4 „	cabbage.
		and $\frac{1}{4}$ „	castor oil meal.*

The concentrated food and the potatoes were mixed together and fed morning and evening. The cabbage was given uncut at mid-day.

For the first few days the hogs did not quite clear up all their ration, so for a week only two-thirds of the amounts mentioned were fed, after which the full ration was returned to and no difficulty was experienced in getting the hogs to clear up. The supply of tail meal ran out on 23rd November and was replaced by an equal weight of sharps. On 4th December, after an interval of 14 days, the hogs were again weighed, but the results, with the exception of Pen III., were not quite so satisfactory as they had been at the end of the preceding fortnight. (See Table I., cols. 5 and 6.)

The concentrated ration was altered on 4th December—

Pen I. getting 1 lb. home-grown linseed cake,† 1 lb. coconut cake, and 1 lb. sharps;

Pen II. getting 1 lb. imported linseed cake,† 1 lb. coconut cake, and 1 lb. sharps; and

Pen III. getting the same as Pens I. and II., except that $\frac{1}{4}$ lb. castor oil meal was used instead of the linseed cake.

On 10th December, kohl rabi were used to replace cabbage, and after a few days it was found that the hogs would eat more of the roots than they would of the cabbage. By 16th December they were clearing up 6 lb. per day. It was fed roughly chopped, each root being cut into about four pieces. This method seemed more satisfactory than cutting in the machine. It may be that the machine imparts a taste of steel to the roots; but it was always found that the hogs ate the roots in larger quantities and with more relish when they were fed to them roughly chopped.

A fresh supply of palm kernel cake having been obtained, this was now used to replace the coconut cake—weight for weight.

On 18th December the hogs were again weighed, and a study of Table I., cols. 7 and 8, shows that they had been doing well during the 14 days.

In the case of Pens I. and II. 18.8 lb. live-weight increase had been produced at a cost of 42 lb. concentrated food, and in the case of Pen III 15.6 lb. had been produced at a cost of 38.5 lb. of concentrated food. These figures are very satisfactory.

* The castor oil meal* was used by request to test if a new process had removed its poisonous properties; so far we find the meal useful.

† The linseed cake was fed for experimental purposes; it may be replaced by equal parts of palm kernel and coconut cakes, weight for weight.

On 19th December the potato ration of all three pens was raised by 2 lb. to 14 lb. per head per day, and at the same time the castor oil meal given to Pen III. was advanced to 1 lb.

Unfortunately, just at this time, very severe frost stopped the work of sorting the potatoes in the pit, and from 21st December to 2nd January kohlrabi at the rate of 14 lb. per day were used to replace the potatoes.

On 1st January the linseed cake ration of Pens I. and II. was raised to $1\frac{1}{2}$ lb. per day, and the castor oil meal to Pen III. to $1\frac{1}{2}$ lb.

After an interval of 28 days, *i.e.*, on 15th January, the hogs were again weighed, showing satisfactory results. (See Table I., cols. 9 and 10.)

On this date also a rearrangement of rations had to be made. Owing to delays on the railway a fresh supply of castor oil meal had not arrived, and Pen III. was put on to 2 lb. palm kernel cake and $2\frac{1}{2}$ lb. sharps. Pens I. and II. were given an additional $\frac{1}{2}$ lb. sharps. At the same time mangolds were used to replace the kohlrabi, and it was found that the pigs would clear up 7 lb. On 18th January it was noticed that one or two of the hogs were scouring slightly, but a mild dose of salts given in some slop soon put them to rights.

Arrangements being made for the hogs to go to a bacon factory on 4th February, the well-known authority Mr. H. Bell, of Messrs. A. T. Grain & Sons, of Cambridge, examined them on 30th January, and selected 12 as being fit for bacon, but the manager of the factory on being written to asked that all 15 might be sent. Unfortunately, one of the hogs in Pen III. hurt his shoulder and went entirely off his feed for several days.

On 31st January the final weighing was made (see Table I., cols. 11 and 12). The hog in Pen III. that had met with the accident had actually lost weight, so this naturally brought down the average for the pen. At the same time neither of the other two pens had done so well as previously, suggesting that if the pigs had been kept on any longer it would have been necessary to raise the concentrated ration.

On their way to the bacon factory the hogs were exhibited in Cambridge Market, and created a good deal of interest.

On their arrival at the factory they were carefully examined by the manager, and one hog was marked by him as being more suitable for the fresh pork than the bacon trade. The carcass weights were obtained (see Table I., col. 13) and the percentages are given (see col. 14).*

The 15 pigs produced 2,002 lb. pork. After the carcasses had been dressed the manager of the factory reported upon

* Tables II. and III. give the food consumed by the hogs (in Lot A and Lot B) from the time they were weaned to the time they were put up to fatten; Table IV. gives the average daily rations of the three pens during the fattening period from 20th November to 31st January; and Table V. gives the total foods consumed from weaning time to end of the fattening period, and the resulting gain in live weight.

<i>Result :—</i>		
26 weeks grazing	} yielded 162'5 lb. increase.
488 lb. concentrates	
1,721 " farm produce	

them as follows : " Lean meat healthy, good colour and plenty of it. Colour of lean meat nice and delicate, like chicken. Well marbled. Not coarse. Colour of fat good."

In order to arrive at the amount of concentrated food required to produce 1 lb. of *pork*, the food fed to the sows must be taken into consideration.

The sows' spring litters yielded 180 lb. weaned pigs.

" autumn " " 192 " "

A total of 372 " "

During twelve months all the food fed to the sows had been weighed, and it was found that they had on an average consumed 1,285 lb. of concentrated foods, *i.e.*, 1 lb. of pigling cost 3'45 lb. of concentrated food. The piglings averaged at weaning 30 lb., so that up to that time they had cost 103'5 lb. of concentrated foods. Table V. shows that 162'5 lb. of bacon hog cost 488 lb. of concentrates, so that up to the day of slaughter the hogs had consumed 591'5 lb. of concentrated food. As they averaged 133'3 lb. *pork* (Table I.), 1 lb. of *pork* was the equivalent of 4'4 lb. of concentrated food.

It is important to note that not a pound of this food was fit for human consumption.

RATS: HOW TO EXTERMINATE THEM.

PART II.

R. SHARPE.

(Concluded from last Month.)

Uses of the Snare.—The snare is a very suitable means of taking rats after the attack with poison has been carried through, that is, presuming that the original conditions required such drastic treatment. The snare is harmless to game and poultry and does not call for the regular attention which is so essential in the case of traps. Snares need not be visited early and late, the reason being given in picture form in Fig. 1. Fig. 2 explains how the plans are laid for producing so satisfactory a result. The jerk of the bent stick draws the noose tight round the rat's neck, so that when caught it is quickly strangled. When rats are taken in a trap there is always the risk that they will twist off their feet, but no equivalent opportunity for escape occurs in snaring. Snares must, of course, be visited every day for the purpose of re-setting those which have made catches, at the same time making sure that the others have not been disturbed in the interval. A very important duty when dealing with snares, and for that matter with all other catching apparatus, is to dispose promptly of the rats. These should be buried deep down, as nothing more quickly tends to make the survivors "wary" than the leaving of their deceased companions in the vicinity of the operations. Such a hint would hardly seem to be necessary, but experience suggests that the precaution recommended is often neglected. Slinging them by the tail into neighbouring clumps of brushwood is nearly as bad as leaving them near the trap, or snares, for nothing is more offensive and objectionable than decaying rats. Snaring is not to be recommended when large quantities of rats are about, the survivors becoming "snare shy" before the work is half through.

A Necessary Precaution for Novices.—The bender is a springy stick pointed at one end and firmly planted in the ground so that it shall jerk into the upright position when a rat is caught. When setting a snare care should be taken to keep clear of the bender, for if it should happen to be released unexpectedly it may hit the snarer in the face with possibly serious results. So grave, in fact, is the risk that I should always advise the novice to take a very simple precaution which makes such mishaps impossible. The device I recommend consists mainly of a peg some 9 in. long, carrying a short crook at the

top formed from a side branch. The hazel grows many natural crooks of this sort. To the crook must be firmly attached a length of stout string, about 18 in. long, having a loop at the free end. The peg is driven into the ground immediately below where the bender will eventually be held down. The string is carried over the bender, the loop being threaded over the crook on the peg. The bender is thus prevented from rising higher than 9 in. off the ground. With this device in use the snare can be set with safety, and it should not be dispensed with until such time as the habit of avoiding the radius of the bender has become second nature. The novice should do all his adjusting and testing of the snare with the safety apparatus in place; but he must never forget to remove it when all is complete, otherwise any rat which enters the snare with blocked mainspring, so to speak, escapes for the time being.

Description of the Snare.—Apart from the bender, of which only the extremity is shown in the illustration, the other wood parts are the "teeler" and the "ground peg." The teeler is a piece of stick about the thickness of a lead pencil. It should be made 4 in. long, and one end of it must be split so as to provide a holding for the wire noose. The split end is known as the grip, the illustration clearly showing the manner of pointing the end. The opposite end to the grip is cut flat above and below, the shape given being such as to ensure a firm seating in the notch cut in the ground peg, and a proper bearing for the overhanging hook. The ground peg may be made about 10 in. long, though if the soil is light or soft a much longer peg is necessary. In hard ground a rather shorter peg suffices. The peg must be forced into the ground so that the notch is about 1 in. clear of the surface, the teeler being thus given a position which will enable the noose to be arranged over the run at a height of about $\frac{3}{4}$ in. The formation of the ground peg is sufficiently explained by the illustration, and its function, together with that of the various other parts, will also be apparent. Practical work in setting, and testing when set, will supply all necessary guidance as to the best shape for the notch, the amount of overhang of the projecting arm, and other details. The combination works as a delicate catch for holding down the bender. A rat running into the noose releases the catch, with the result that the noose is drawn tight with a jerk, the rat being swung clear off the ground in the process.

The function of the various parts having now been referred to in a general way the detailed description may continue. Having cut the teeler the next process is to take a piece of

FIG. 2.--RAT SNARE.

Artistic licence has been exercised in leaving visible the details which the careful trapper always arranges to conceal from view.

parcel string 12 in. long and to form at one end of it a loop 1 in. long. This loop forms the attachment with the bender. Next the string must be tied round the middle of the teeler, the knot being so arranged that there shall be a straight pull against the hook of the ground peg when the tension of the bender comes into play. If the knot is set to one side or the other the pull of the bender causes the teeler to sit uneasily in the notch. When the string has been correctly attached to the teeler a free length of $3\frac{1}{2}$ in. is available for fastening to the wire noose. The knot having been tied, about $1\frac{1}{2}$ in. of string separates it from the teeler. Some 13 in. of ordinary snaring wire is required to form the wire noose. A single thickness suffices, the eye being formed by twisting one end. As an alternative, double this length of extra thin wire may be used, the ends being brought together and the two twisted lightly around one another, all as shown in the illustration. There is no objection to the wire being double, provided it is very thin, though on the whole I prefer a single thickness. If there has been no waste of wire in making the knot sufficient remains for a loop of about $2\frac{1}{2}$ in. diameter, with in addition a short length of wire leading to the knot. This portion of the wire must be fixed in the cleft of the teeler and be so inserted with reference to the loop that the eye comes on top. Fig. 2 will explain what is meant, for obviously the noose would be liable to sag if the wire passing from the teeler took the high road instead of the low road. The bender is of about the stoutness of an ordinary walking-stick. Its length is 5 ft., and it may be of ash or hazel, the latter for preference. If the butt end has about 3 in. circumference the natural taper will give it the right sort of springiness. As a general guide one may say that when bent over it should pull against the ground peg with a tension of three or four pounds. This gives plenty of strength for lifting a full-size rat clear of the ground. A stiffer bender is to be avoided because it makes what I might call a hard trigger pull ; in other words, the rat's task in pulling at the snare must not be made too difficult.

On Setting a Rat Snare.—In choosing a spot for setting a rat snare one should first of all make sure of enough grass to conceal the machinery. This is the only detail where the illustration misses reality, artistic licence having been taken to enable the reader clearly to see the details. The less that can be seen of the peg and the teeler from the point of view of the rat the better. The wire then represents no more than a piece of tangled herbage, like fifty others through which the rat is in the

habit of forcing its way. The bender cannot be hidden, but it is hardly of a nature to cause suspicion.

As already stated the dimensions given for the various parts of the snare permit of the loop having a diameter of $2\frac{1}{2}$ in. with its lower sweep about $\frac{3}{4}$ in. above the run. The ground peg should be placed about $4\frac{1}{2}$ in. from the side of the run; and as the teeler is 4 in. long its grip end just fails to overhang any part of the run. As rat runs are always narrow and well-defined the $2\frac{1}{2}$ in. loop will just cover the whole width of the run and no more. Having fixed the peg so as to comply with the above requirements the bender must be planted in the ground some 4 ft. back. This should bring it into the proper position when bent over ready for attaching to the string. Care and practice will enable the novice so to plant the bender that it gives a true vertical lift to the string. Having fixed the bender the safety peg described in the separate note must be put into place. The end of the bender should always be notched or otherwise treated so that the weight of the rat shall not cause the loop to slip. The teeler is now ready to be inserted into the notch of the ground peg. In making the final adjustment care must be taken that the setting shall be sufficiently light to ensure immediate action of the snare the moment a rat puts its head in the loop.

To Deal with Snare-Shy Rats.—When results suggest that rats have become shy of going near snares a stratagem similar to the one recommended for traps should be adopted. In cases of this kind—and, in fact, at other times as well—I set the snare in all respects complete except for the correct placing of the nose. On such occasions four or five of the main runs are selected, places in them being chosen where there is a good covering of grass to hide the ground peg. The whole snare is then set up in the proper position, with in addition the safety peg and string to prevent accidental release. The wire loop, instead of being laid across the run, is bent close up to the teeler so as to leave the run quite clear. The rats are then able to use the run freely, and they soon forget the slight disarrangement of the surroundings which has taken place. The "foil" also has an opportunity to clear off. After the snare has been a couple of nights in this condition, with a piece of stick I push the wire back across the run, at the same time removing the safety peg. The results as a rule generously repay the extra amount of time and trouble taken.

The Terrier for Rat Catching.—To leave out the terrier would be to commit an injustice on a most capable assistant in a good

cause. My acquaintance with working terriers is not less thorough than with the metal and wood implements for catching rats. Poison must stand supreme as the only means of ridding neglected land quickly and with a small expenditure of effort of the majority of its rat population. Trap and snare can alone follow afterwards for reasons which will be apparent when explained. The ardent lover of dogs would hardly care to turn them loose on land which had just been poisoned, for certainly not less than 60 per cent. of the poisoned rats would be lying dead in their holes and other places of refuge. Of the remaining 40 per cent. that die in the open many would not be gathered. To turn ferrets into such holes to give the dogs their chance would mean that the ferrets would simply gorge on the dead carcasses, and this with fatal results in the case of many kinds of poison. Some terriers would be inclined to mark holes containing dead rats, but an old and knowing dog might be relied upon to pass them by. All told, I cannot quite see where the terrier comes in during the actual poisoning campaign and the period immediately following. Where for various reasons poison is inadmissible the terrier is invaluable. The terrier may be given credit for the ability to hunt out the last rat, but also for the even more important duty of dealing with the first fresh arrival to appear on premises which have been cleared. Should this happen to be a doe the service performed is invaluable.

A really keen ratter will often be the first to proclaim the presence of a rat on premises where such is not believed to exist. There may be no mistaking his excited bark when he has located his game, perhaps under the corn-bin or the water-butt, or often in a heap of faggots, such places forming a favourite shelter to these rodents. The barks and yaps may become louder and louder until he has succeeded in attracting someone's attention, past experience telling him that assistance is necessary on such occasions, in the form of poking with a stick until the rat decides to bolt, a kill following in due course. Rats, when disturbed at dusk in the course of their search for food, nearly always make for these handy shelters, and they remain in them until quiet is once more restored.

Rat Hunts after Dark.—It will prove useful to hunt for rats after dark, always provided that the terriers are good at the work and quick killers. One or two hurricane lamps are most useful on such occasions. A lamp of this sort placed on the ground so that it may throw a steady light will suffice to command some chosen spot which rats are judged likely to

cross. One man in a position commanding the lighted area holds the dog quite loosely whilst a second man, if possible with another terrier, works towards the prepared spot. The moment a rat crosses and is perceived by the dog it breaks loose and takes it. Some really fine hauls may be obtained in this way, and the many in which I have taken part prove that they encompass the destruction of many rats. The short feeding holes to which rats are in the habit of retiring to devour unmolested any tit-bits they may have found are nearly always to be found in fowl pens, or on the plots where fowls are fed when feeding is done outside. If a visit is paid to such enclosures after dark, the disturbed rats will take refuge in the small holes in the same manner as if they were faggot heaps, that is provided they are not already inside indulging in a meal. A good dog will, of course, scent them out. I have often known as many as seven or eight obtained in a single night this way, holes in enclosures of one sort and another being as a rule the best places to search, no doubt because access to them is not possible to dogs and cats. Rats should not be dug out of such holes, should they refuse to budge under the persuasive influence of a stick. A bucket of water poured down the hole brings them to the surface at once, so leaving intact a most useful rat-made death trap. Against digging at any time is the fact that this kind of disturbance of the haunts of rats breeds suspicion and makes them much more difficult to catch afterwards.

Rats Feeding on Stubbles.—There are many, no doubt, who have noticed the same kind of feeding hole which is mentioned above situated in stubble-fields, more especially before the corn has been carried. A favourite place for these holes is at the base of the stooks. Here of all places is the champion hunting ground for the ratting terrier. A moonlight night should be selected for such excursions, and the field of battle should be approached from a direction which cuts off the line of retreat to the holes of the rats. The necessity for this line of approach will be obvious ; for to start operations from any other direction would send the rats scampering away to their stronghold. When it happens that burrows are fairly evenly distributed on all sides of the field the only possible plan is to start from one side on one night, from another the next night, and so on until each set of inhabitants has been dealt with in turn. Rats will not, as might be supposed, betake themselves to strange shelters when a raid is on. Rather, they crouch under stooks or go to earth in available

feeding holes. Excursions of this nature should not be postponed till after the corn has been carried, for the stooks form so favourite a retreat, and are so vulnerable to attack, that the opportunity they provide should not be missed. In fact, the earlier the date of the visit after the corn has been cut the better, because as soon as the rats have accumulated food hoards in their burrows the less likely are they to betake themselves to the open fields. Though much corn lies about after carrying, in the form of gleanings, the fact remains that the loss, maybe, of convenient shelter, drives them elsewhere. Whatever the explanation, they are much diminished in number when the field has been cleared. A couple of good terriers are essential if excursions of this nature are to produce results in proportion to the opportunities provided.

Using Ferrets with Dogs.—Terriers are invaluable when rats are being turned out of their holes by the aid of ferrets. There are doubtless many owners of good working terriers who are unversed in the methods of teaching a dog not to touch a ferret. A tip or two on this subject will, therefore, not be out of place. If the ferrets are under the same ownership as the dog, the dog should always accompany his master when he goes to feed the ferrets. At such times the ferret should be taken out of the hutch, the dog being always given an opportunity to smell it. To avoid accidents the ferret must be so held that it cannot bite the dog; the dog in its turn being warned, "'ware ferret," or chided with a severe "no" should it make the least attempt to snap at the ferret. If this routine is carried out for a few days, the dog soon learns to look upon the ferret as a friend. The next stage of education is to place the ferret on the ground, allowing the dog to watch it run about. When real work begins a dog so taught will have already begun to realise what is expected, but even then the final precaution should be taken of holding the dog when it sees the ferret at work for the first time, and it should only be released when the first rat bolts. Provided the early stages of education are passed without any accident such as would breed enmity between dog and ferret, the two very soon learn to work amicably together.

Precautions to be Observed with Ferrets when Used in Buildings.—Care should always be taken to avoid putting ferrets in holes which may be suspected of leading to the roof. The climb is generally quite easy, but the return journey may offer difficulties which the ferret fears to face. A ferret so lost may remain in the roof for days, hunger ultimately forcing

it to seek some easier route of escape. If perchance the one chosen leads to the fowl-house or duck-pen, or even to a coop of chicks, the results will be disastrous. What so often happens to cause ferrets to get lost in buildings is that they are placed on the wall-plate where a rat has been seen to run, and they follow the scent regardless of difficulties, the rat being the better climber usually escaping. The problem of return then breeds fear in an otherwise courageous animal.

Introducing a Terrier to its First Rat.—Care must always be taken to give a dog a fair chance when first brought face to face with a rat. Sometimes people are so foolish as to expect a dog to kill its first rat when the latter is held in a gin, the two being so placed that the dog may see the rat. To encourage a dog to attack under such circumstances is sheer madness. In cases of this kind it very often happens that a dog gets bitten, but if game it will fight on in the hope of gaining a more effective grip of the rat. In so doing it will almost surely bite the trap at the same time, the pain so inflicted causing the dog to let go, when it may again be bitten. Not only is the dog badly punished in the process, but it may break one or more teeth against the trap, so destroying some of its usefulness afterwards. A dog which persists in attacking under such unfavourable circumstances is surely too good to spoil. Rat-bites so inflicted are especially dangerous, not only because of the desperation of the rat, but because in its previous endeavours to escape it is sure to have soiled its teeth with untold filth scraped from the rusty trap. One puppy which I well remember died a few days after such an encounter. When a dog or a ferret gets bitten by a rat the wound should be promptly cleaned and disinfected with Condy's fluid. As time counts for everything, a syringe should (if possible) be carried on the person, together with a small bottle of the chemical, the object of the syringe being to drive the fluid the whole depth of the puncture made by the rat's teeth. The plan I always adopt for introducing a young dog to rats is to procure a live one and take it out into the middle of a field. Then I liberate the rat, releasing the dog when the rat starts making off. If the dog is one of the right breed it will make short work of the quarry. Though it may get bitten in its novice encounter even when the conditions are properly arranged, the danger of after-effects is by no means serious. In fact, I am not sure that a "pinch" at the beginning is not an important part of the training, as it teaches the dog from the very commencement the importance

of getting in the first bite. Condyl's fluid will allay all risks of spoiling a good dog thus early in its career.

Terriers in Relation to Poison.—Perhaps a few final remarks will make quite clear the separate duties of poison and terriers. Everybody must realise that there are believed to be about as many rats as human beings in this country. They exist everywhere, around the docks, wharves, and other places where food is handled and stored in the outskirts of towns, and in the country proper. The agricultural rat, with which I am mainly concerned, is to be found both around the farm buildings and rick-yards, and in the hedgerows and open spaces. It moves from one situation to another according to the season and circumstances. There is undoubtedly a very strong prejudice against the use of poison. This dislike of the only effectual medium for use in the open country may be explained in a variety of ways. First of all the only organised attacks on the rat population have taken place in the sea-port areas, where the rat is mainly considered as a spreader of disease. To poison rats in granaries, and some might add farm buildings, is not the same thing as to poison them in hedgerows and ditches. Authority is thus against poison in general, though the dislike is based on experience of one kind of place only. I do not know what method is used in places where poison is barred ; but the survivors of whatever process is applied are remarkably numerous and flourishing. Now poisoning is a "keeper's" method, and as such it is seldom mentioned except in whispers, but when it has been properly applied there are no rats, flourishing or otherwise. Surely the moral is obvious. Now, I have already pointed out the objections to setting terriers to work, with or without ferrets, immediately after a poisoning campaign, and that is why I did not mention them when outlining my plan of poisoning followed by trapping and snaring. But, assuming there are places where it has not been deemed advisable to lay poison, and there must be many, or others where outlying colonies of rats have been overlooked, then the terrier comes into its own. As has been made quite clear above, poison cannot be used repeatedly on the same ground, therefore in the long intervals between poisoning campaigns the terrier will have ample opportunity to prove its worth.

Wounded Soldiers Might be Taught Rat-trapping.—Many forms of employment have been suggested for wounded soldiers, but I can imagine none that would better suit them than rat-trapping. The open-air life, the hourly interest of their pursuit,

the necessity to pit brains against cunning, these are all on the right side, whilst the work itself is not of an exhausting nature. Wounded soldiers could be readily taught the art of taking rats by means of the snare, the water-pit trap, and the ordinary gin. With the continuous attention they would be able to devote to the task I am confident that any intelligent one of their number could in a short time rid any farm of the last rat which had survived a poisoning bout—not only rid the place, but keep it constantly clear by having a certain number of pit-traps constantly set. Fresh-comers would more readily fall victims than local inhabitants. With the aid of a "bike" one man could attend to a whole parish, and no finer combination of pleasure and business could be imagined.

MOLE-PLOUGHS WORKED BY HORSES.

THE necessity of greatly increasing the area of arable land has resulted in a considerable extension of the practice of mole-draining. Fields having a uniform heavy clay subsoil can by this means be effectively drained at a total cost of 20s. to 30s. per acre, and the drains are often quite efficient at the end of 15 or 20 years. As a rule mole-draining is done by steam-tackle, and where this can be employed it is undoubtedly advisable to do so. There are, however, cases where the necessary equipment is unobtainable or where the fields are too small to make its use an economic proposition and, in such cases, a simple form of mole-plough operated by horses might often be used with satisfactory results. The attention of the Board has recently been called to two such ploughs which have been successfully used for many years in Buckinghamshire and Essex respectively.

The two ploughs are in all essential respects very similar. Each consists of a strong wooden beam fitted with stilts like those of an ordinary plough. In the centre of the beam is inserted a stout iron blade or coulter sharpened to a cutting edge in front. To the bottom of this is fitted a torpedo-shaped mole of the usual type. The cutting depth is about 18 in. in one case and 22 in. in the other, but additional depth is secured by throwing out one or two furrows with an ordinary plough along the line of the proposed drain before using the mole. The distance between the drains is determined to a great extent by the width of the "lands" or "stitches," but about 5 yards is common.

FIG. 1.---Details of Mole Plough (scale $\frac{1}{2}$ in. to 1 foot). Above: Plan of underside, showing sole-plate. Below: Vertical section.

FIG. 2.—Details of Mole Trough (scale $\frac{1}{4}$ in. to 1 foot). \bar{L} , Horizontal section.

FIG. 3.—Plan of Anchor.

FIG. 4.—Side View of Anchor.

The mole-plough is drawn up the field by means of a steel rope attached to a winding drum. In one of the ploughs this is a drum taken from an old ploughing engine; in the other the drum is made of wood encased in iron. In both cases the drum is fixed to a vertical spindle in the centre of a stout wooden framework. This is provided with two iron anchors to hold the winch firmly in position when the cable is being wound in. The Essex plough has, in addition, two struts, the extra support probably being necessitated by the fact that in this machine the road wheels are not detached from the winch when ploughing is being done.

The winding is done by two horses (occasionally three may be required) yoked to the pole or shafts fitted to the top of the spindle. They move round and round just as in working the ordinary horse-gear attached to a chaff-cutter or other farm machinery. Two men are required, one to hold the plough, the other to look after the horses and see that the rope is wound on properly. When one drain has been completed one horse drags the winch to the top of the next drain, the other drags the plough back to the bottom of the field. If the drain is of greater length than the cable, the winch must be fixed first at an intermediate position and afterwards moved to the top of the drain when all the cable has been wound in. In all cases the plough should be first let into the ground at the lower end of the drain.

The procedure is similar to that adopted when draining by steam-tackle. The outlet is first fixed and then the main drain is laid. As a rule, pipes are used for this and also for the first few feet of the minor drain in order to have a good junction with the main. A hole or eye is left at the point when the mole-drain is to start and the coulter of the mole-plough is inserted into this.

The accompanying drawings show the essential features of the Buckinghamshire plough which was constructed at a low cost by a local blacksmith and joiner. The Essex plough was also practically rebuilt locally but its origin is unknown. It is not suggested that such ploughs should be used where steam-tackle can be employed, as the latter is much more expeditious; but where it is not available, or for various reasons cannot be used, ploughs of the kind illustrated might with great advantage be constructed. The saving as compared with pipe-draining is immense, as 2 men and 2 or 3 horses do an acre a day.

This does not include the preliminary ploughing or the subsequent replacement of the furrow thrown out by the ordinary plough before the mole-plough is used.

THE CONTROL OF PESTS OF FRUIT TREES IN GARDENS AND SMALL ORCHARDS.

**TO KEEP FRUIT TREES FREE FROM PESTS IS AS IMPORTANT AS
DIGGING OR HOEING.**

In the following calendar **bold type** shows the minimum work which must be done to make sure that fruit trees escape the attacks of their chief pests. To make still more certain the work indicated in ordinary type should also be performed.

GENERAL ROUTINE OF WORK.

To be supplemented by special methods when epidemics occur.

Month.	Kind of Fruit.	Application.	Reason.
October ..	All trees ..	Grease Band (1)	To catch female Winter Moths (2).
Oct.-Nov.	All trees and bushes.	Prune	Cut out all diseased wood.
Dec.-Feb.	All trees ..	Caustic Soda or Lime-Sulphur	Apply once in three years to keep the trees clean.
March ..	Apples, pears, plums.	Lime-Wash .. or	Lime Wash cleans the trees and also prevents Aphis (3) and Apple Sucker eggs from hatching: apply it when the buds are opening.
April ..	All trees ..	Nicotine and Soap.	Apply just before flowers open if attacks of Caterpillars, Aphis or Apple Sucker are anticipated, and the trees do not require cleaning.
April ..	All trees ..	Arsenate of Lead.	Apply directly flowers have fallen, if Caterpillars are still causing trouble.
End of April or May.	Apples and pears.	Bordeaux Mixture or Lime-Sulphur.	1st application to prevent Apple and Pear Scab (4) and American Gooseberry Mildew (5). Spray directly the petals have fallen. Make a second and third application (if necessary) at intervals of 3 weeks.
April ..	Gooseberries.	Lime-Sulphur ..

(2) See Leaflet No. 4 (*Winter Moths*).

(3) See Leaflet No. 308 (*Plum Aphis*).

(4) See Leaflet No. 121 (*Apple and Pear Scab*).

(5) See Leaflet No. 195 (*American Gooseberry Mildew*).

THE CONTROL OF PESTS OF FRUIT TREES IN GARDENS AND SMALL ORCHARDS.—The object of this article is to describe the best and simplest methods of preventing the common pests of fruit trees from causing widespread damage to trees and fruit.

In controlling fruit-tree pests it is, of course, of great importance that the identity and life history of each pest should be known. Information on these points may be obtained from the various leaflets to which reference is made in this article; but in cases of difficulty specimens for identification should be sent either to the nearest Agricultural Institution or to The Director-General, Food Production Department, 72, Victoria Street, S.W. 1.

The packages containing the specimens should be marked plainly: "*Pathological Laboratory*," and, whenever possible, a piece of the plant showing the nature of the damage should be sent, together with examples of the pest. The specimen should be packed in a tin box, so that the contents may arrive in fresh condition. No holes should be made in the box.

Methods of Controlling Pests.—The chief pests of fruit trees are certain insects and lowly forms of plant life known as fungi. In addition to insect and fungus pests, mosses and lichen which grow on the bark also do damage, particularly by harbouring insect pests.

The insect pests which attack fruit trees are of two kinds :—

1. Biting insects, that is to say, insects which eat the solid parts of the plants, as, for example, the leaves, using their jaws to bite off their food.
2. Sucking insects, that is to say, insects which make punctures in the surface and suck the sap through a trunk or proboscis. Sucking insects have no biting jaws.

This distinction between biting and sucking insects is important from the practical point of view. Insects which bite their food may be destroyed if the fruit tree which they attack is sprayed with an "internal poison insecticide," that is to say, an insecticide which on drying leaves a film of poison on the surface of the leaves and other vulnerable parts of the tree. The biting insect sooner or later eats the poison thus deposited and is destroyed. The insecticides used as internal poisons are often harmless to insects unless they are actually eaten. This point is worth mentioning, owing to the fact that those who use these internal poison insecticides are surprised when they find that an insect pest dipped into the poison is not killed.

For sucking insects internal poison insecticides are useless, for the insects feed on the sap of the plant, and the poison sprayed on the surface never reaches the sap. A different type of insecticide is therefore necessary, and the insecticide which is used for destroying sucking pests is of the type known as a "contact insecticide." Such an insecticide only kills the

insects which it actually touches. It destroys either by poisoning them through their breathing pores or by enveloping them in a substance which prevents them from breathing or moving.

Therefore as a general rule for biting insects, such as caterpillars or beetles which are causing damage, use an "internal poison insecticide," but when the fruit tree is attacked by sucking insects such as Aphides (green fly), a "contact insecticide" must be used.

Cleansing Washes.—In order to get rid of the moss and lichen which accumulate on tree trunks, and serve as harbouring places for insect pests, a cleansing wash should be used either in the winter or early spring. A cleansing wash will also serve to destroy a certain number of insect and fungus pests.

Another practice which will help to keep fruit trees clean is the systematic gathering of fallen fruit, for many pests which feed inside fruits cause the fruit to fall prematurely, and in these cases the insect pest, usually in the grub stage, is contained within the fallen fruit. Therefore if the fruit is not fit for human consumption it should either be given to pigs, thrown on the bonfire, or buried so deeply as to kill the grubs and so reduce the chance of an attack next year.

Fungus Pests.—The two chief measures to be taken to reduce the damage done by fungi which attack fruit trees are, first, the pruning out of dead or dying twigs and branches and, second, spraying with a suitable fungicide. The importance of pruning in keeping down the fungus pests is due to the fact that many of the fungi which attack fruit trees make their way into the tissues of the twigs and branches. When they have penetrated into these tissues they cannot be reached or destroyed by spraying, hence the only remedy is to cut out and burn the diseased portions, taking care to cut back to healthy wood. If this is not done the fungus continues to live, and by producing spores it may give rise to infection in other parts of the same tree or in other trees near by. These spores or fungus seeds are produced at certain times of the year on the surface of the diseased twigs, branches or leaves. If the fungicide is applied at the right time, many spores on the point of germinating will be killed outright; moreover, the spray fluid on drying forms a thin film of poison on the plant which is then protected from any fungus spores which may fall upon it and begin to grow. The essence of this treatment, therefore, is to apply the fungicide before the fungus has had time to reach or begin to grow on the plant.

In addition to this preventive spraying, it may be possible in certain cases when the fungus lives on or near the surface of the plant, as for instance in the case of the mildews, to check the disease by spraying after the fungus has begun to develop, but even here, owing to the difficulty of wetting a thick felt-like covering of fungus, it is preferable to spray as a preventive rather than a cure.

Pests Here Dealt With.—The following is a list of the crops and pests dealt with in this article :—

APPLE :

certain well-known crops, such as raspberries and red currants, are also passed over.

Formulæ for Making Washes.—In the preceding section mention has been made of

- | | |
|-----------------------|-----------------|
| (1) Cleansing washes, | (3) Fungicides, |
| (2) Insecticides, | |

and it is convenient to deal with these classes separately, though it must not be forgotten that one wash may have a double value—for instance, a lime wash is both a cleansing wash and an insecticide, while lime-sulphur, generally used as a fungicide, has also insecticidal and cleansing properties.

1. *Cleansing Washes.*—Where trees are overgrown with moss and lichen a cleansing wash should be used. Washes made according to the first (a) and third (c) are applied during the winter and early spring, before the buds have burst. Lime wash (b), however, may be applied at any time until shortly before the blossoms open—the later applications having greater insecticidal value.

- | | |
|--------------------------|---------|
| (a) Caustic soda | 2 lb. |
| Water | 10 gal. |

The best form of soda to use is "powdered" caustic soda, purity 98 per cent. Dissolve in a little water and dilute to the proper strength. In the application of this wash great care must be taken that it does not touch the hands or face as it is extremely caustic. Thick gloves, preferably of rubber, should be worn. Caustic soda is likely to be very scarce and, except in the worst cases, one of the other cleansing washes should be used.

- | | |
|----------------------------|-----------|
| (b) Best quicklime | 10-15 lb. |
| Water | 10 gal. |

Obtain only the best quicklime and store carefully to prevent it from air-slacking. Builders' lime, which is often partially air-slaked, should not be used.

Slake the lime with a little water and when slaked into a fine powder add the remainder of the water, stirring vigorously the whole time. Strain at least twice through sacking before filling the spraying machine. Keep well agitated throughout the application. This wash should be used freshly prepared.

- | | |
|--|---------|
| (c) Lime-sulphur (1·3 sp. gr.) | 3 qt. |
| Water | 10 gal. |

Add the concentrated lime-sulphur (1·3 sp. gr.) solution, which may be bought ready-made, to the water and stir well. This wash should be used freshly prepared. Never use a

spraying machine with any copper parts as the lime-sulphur reacts with the copper.

When lime-sulphur washes are used in the summer they should not be of this strength but diluted as given on p. 48.

2. *Insecticides*.—These washes have already been divided into "contact" insecticides and "internal poison" insecticides.

(a) *Internal Poisons*.—Internal poisons act by poisoning the insects' food. They are used for all the leaf-eating pests. Arsenate of lead, in paste form, is recommended. The formula is : lead arsenate paste, $\frac{1}{2}$ lb. ; water, 10 gal.

This wash should be applied in a fine spray. The object should be to wet all the leaves without drenching them, so that when the leaves have dried they will be covered uniformly with poison.

Full details for making this wash are given on the jar containing the paste.

(b) *Contact Insecticides*.—These kill insects, not by poisoning their food but by contact with their bodies. To attain this, the washes should be applied with as much force as possible and with a coarse spray.

A wash containing nicotine is advised. Although expensive it is the most effective contact poison. It also has considerable value against caterpillars when young.

Soap should be added, not only for its insecticidal properties but chiefly because it causes the wash to "run" on the leaves instead of remaining in drops.

Nicotine may also be used in combination with lime-sulphur or arsenate of lead, the nicotine being added to the diluted lime-sulphur or lead arsenate wash at the rate of $\frac{3}{4}$ oz. to each 10 gal. of wash ; in these cases no soap should be used.

The formula for nicotine soap wash is :—

Nicotine	$\frac{3}{4}$ oz.
Soap (soft)	$\frac{1}{2}$ lb.
Water (soft)	10 gal.

If the water is hard, 1 lb. of soap should be used. Dissolve the soap in hot water, dilute to the required strength, add the nicotine and stir well. If soft soap is unobtainable hard soap should be used instead. There are many satisfactory proprietary contact insecticides on the market which may be used instead of this wash.

Nicotine is a very Deadly Poison, and great care must be taken when using it. Empty nicotine bottles must be destroyed. Nicotine washes, however, only retain their poisonous properties for a few days after having been sprayed on trees.

NOTE.—**Nicotine and Lead Arsenate are Powerful Poisons.** Lead arsenate should not be used where vegetables are grown underneath fruit trees, or where gooseberries are grown, if the fruit is to be picked green. If nicotine is applied, a fortnight should be allowed before the vegetables or green fruit are gathered.

3. *Fungicides*.—Bordeaux mixture or lime-sulphur (summer strength) are recommended. Burgundy mixture—the usual *potato* spray-fluid—made from copper sulphate and washing soda, should *not be used*, as it often causes scorching.

Fungicides should always be applied as preventives rather than as remedies. Attacks by fungus develop rapidly, and appear to a greater or less extent each year according to weather conditions, and when once a disease is rampant it is difficult to check and control. The best way to prevent an attack is to cover the vulnerable parts of the tree—the leaves, fruit and young wood—with a fungicide, and in this way prevent the development of the disease.

To obtain this protective covering, the fungicide should be applied as a very fine spray. Spraying should cease as soon as the leaves begin to drip.

It is usual to give one or two applications of the fungicide, but in cases where a bad attack is expected three applications are required. The first application should usually take place as soon as the petals have fallen and the remaining applications at intervals of three weeks.

(a) *Bordeaux mixture*:—

Copper sulphate	13 oz.
Best quicklime (90 per cent. Cao)	13 "
Water	10 gal.

Dissolve the copper sulphate in water at the rate of about 1 lb. to 1 gal. This should be done in a wooden receptacle. Slake the lime to a fine powder with a little water in another receptacle. Add water gradually to make a "milk," and then dilute to the required amount (9 gal.) stirring well throughout.

Pour the copper sulphate solution into the diluted milk of lime and stir for about 5 minutes. Use the mixture within 24 hours and preferably as soon as made.

(b) *Lime-sulphur* (summer strength):—

Lime-sulphur (1·3 sp. gr.)	3 pt.
Water	10 gal.

Pour the lime-sulphur into the water and stir well. Use this wash freshly prepared.

On certain varieties of apples and gooseberries (see pp. 49 and 51) Bordeaux mixture and lime-sulphur (summer strength) should not be used as they are liable to cause leaf-scorching, and lime-sulphur at half summer strength should then be substituted. It is made as follows :—

Lime-sulphur (1·3 sp. gr.)	1½ pt.
Water	10 gal.

Plan of Operations.—The general *winter* treatment by pruning out dead wood, etc., has already been indicated. During the pruning dead fruits as well as the prunings must be collected and burnt, and on no account be left on the trees. Parts of apple and pear trees affected by canker should be cut or pared away and the wounds dressed with Stockholm tar; this substance is also useful for applying to large wounds made in pruning. Wood affected by Apple and Pear Scab* or Brown Rot† must also be cut away and burnt, and the same treatment applied to twigs of apple trees attacked by Apple Mildew‡, and gooseberry bushes attacked by the American Gooseberry Mildew§.

If the trees are overgrown with moss and lichen use a caustic wash, but in most cases, in view of the scarcity of caustic soda, a lime wash applied later is preferable. Lime-sulphur at winter strength may also be used instead of these washes, but it has less insecticidal and cleansing effect except for Brown Scale attacks on gooseberries and currants.

Apart from the above winter treatment each crop must be dealt with separately.

Apple.—If the trees are somewhat mossy and require cleaning a lime wash should be used—at any time from the middle of March until a week before the blossoms open. Late lime washing may cause a slight browning of the opening leaves, but the injury is not of importance, and the late applications should check to a large extent both *Aphides* and *Apple Sucker*. *Winter Moth* is troublesome in most seasons, and may be dealt with in two ways. First, a nicotine-and-soap spray applied just before the blossoms open will give a fair control of Winter Moth, and will also destroy Aphides, Sucker, and Capsid Bugs.|| Therefore, when lime wash has not been used, a nicotine-and-soap spray is especially valuable. Secondly, if lime wash has been applied, then Aphides and Sucker are less likely to do

* See Leaflet No. 131.

† See Leaflet No. 204.

‡ " " 312.

§ " " 195.

|| In order to control this troublesome pest effectively a second spraying with nicotine and soap should be given as soon as the petals have fallen.

harm, and it is possible to concentrate on the Winter Moth by using lead arsenate either just before or just after the blossoming period (on no account when the flowers are open).

All other caterpillars may be destroyed by lead arsenate, and when young a good percentage may also be killed by nicotine and soap. After the petals have fallen, in gardens where Scab is bad, the trees should be sprayed with Bordeaux mixture or lime-sulphur, but it must be remembered that certain varieties are liable to damage by Bordeaux mixture, as for example: *Cox's Orange Pippin*, *Duchess' Favourite*, *Beauty of Bath*, *Gladstone*, *Miller's Seedling*, and *Lady Sudeley*.

For these varieties, with the exception of Cox's Orange Pippin, lime-sulphur at summer strength should alone be used. Cox's Orange Pippin should only be sprayed with lime-sulphur at half summer strength.

To obtain an efficient control of *Scab* (a) it will probably be necessary to apply a second spraying three weeks after the first. It is worth noting that for the control of caterpillars, lead arsenate may be used in combination with either lime-sulphur or Bordeaux mixture, the lead arsenate paste being added at the rate of $\frac{1}{2}$ lb. to each 10 gal. of the diluted fungicide mixture. If *Scab* is not troublesome, spraying should seldom be required after the apples have begun to swell. During the summer, dead trusses of bloom killed by *Brown Rot* or *Canker* (b) should, as far as possible, be removed altogether with the diseased spurs. If the *Codling Moth* is bad, as may be judged by the presence of many worm-eaten apples during the previous autumn, bands of hay or old sacking should be put round the trunks of the trees in July. The larvæ make their cocoons in the hay or sacking and may be destroyed by removing and burning the bands in winter.

Throughout the season a watch should be kept for *Woolly Aphis* (*American Blight*), and this insect should be dealt with by brushing the affected spots with a little paraffin. Methylated spirit is safer in the case of young trees, but it is difficult to obtain, and on such trees, soap and water used vigorously will do. Finally, at the end of September, the trees must be "grease banded" to catch female *Winter Moth*, and so reduce the pest the following year.

Pear.—The measures described above apply also to the insects listed as attacking pear. There are, however, certain other pests such as the *Pear Leaf Blister Mite* (c) and *Pear*

(a) See Leaflet No. 131. (b) See Leaflet No. 312. (c) See Leaflet No. 239.

Midge (a) for which special treatment is required, and for the treatment of these reference should be made to leaflets.

Plum.—The plum, so far as spraying is concerned, differs from the apple in that the blossoms open much earlier in the season, before the leaves have expanded. Lime wash is nevertheless equally effective against Aphides and may be applied at any time until the blossoms are about to open—for preference within a fortnight or three weeks of that time. If lime wash is applied then, the chief insect pests which remain to be dealt with are the caterpillars of *Winter* and other *Moths*. Lead arsenate is the best insecticide to use, but it is necessary to wait until after the blossom has fallen and the foliage has developed. If lime wash has not been used, an attempt may be made to deal with both caterpillars and Aphides by spraying with nicotine and soap within a fortnight after the petals have fallen. In this case it is not wise to delay too long, as Aphides cause leaves to curl very rapidly and caterpillars are most susceptible to nicotine when quite young. A second application of either lead arsenate or nicotine may be needed if caterpillars or Aphides develop later, but if the work is well done early in the season this should seldom be required. As in the case of apples, grease banding should be carried out towards the end of September,

In the case of *Brown Rot* (b), diseased shoots and dead, mummified fruits should be removed and burnt. Similarly, in the case of *Silver Leaf* (c) affected branches must be cut right out—cutting back to clean, healthy wood and dressing the wound with Stockholm tar. If this work is not carried out before the leaves have fallen, the affected trees and branches must be marked or they may be passed over when pruning in winter. Dead branches or trees killed by Silver Leaf must be burnt as soon as possible. This will remove sources of fresh infection as the fungus only produces spores on the dead wood.

Cherry.—Lime washing may be carried out as in the case of the apple if the trees are dirty. *Winter Moth* should be controlled by grease banding and by the use of lead arsenate after the petals have fallen and as soon as the leaves have developed.

Black Aphides are specially troublesome on wall trees, and as soon as signs of the pest are seen a thorough washing with nicotine and soap should be given; this species of *Aphis* is troublesome to control, and should be dealt with before the

(a) See Leaflet No. 53. (b) See Leaflet No. 86. (c) See Leaflet No. 1302.

tree is thoroughly infested. Shoots attacked by *Brown Rot* should be cut out, as in the case of other fruit trees.

Gooseberry.—Twigs attacked by *American Gooseberry Mildew* (a) should be cut out and burnt during the early autumn. When *Brown Scale* is troublesome, a winter washing with lime-sulphur (winter strength) should be given. In gardens badly affected by *American Gooseberry Mildew* the bushes, with the exception of certain varieties mentioned below, should be sprayed towards the end of April with lime-sulphur at summer strength, care being taken to spray both sides of the leaves as far as possible. A second application should, if possible, be given two or three weeks later.

The following varieties are damaged by lime-sulphur at summer strength, and half summer strength should be used; *Berry's Early*, *Freedom*, *Lancashire Lad*, *Crown Bob*.

The following varieties cannot safely be sprayed with lime-sulphur at all: *Yellow Rough*, *Valentine's Seedling*.

Gooseberry Sawfly is likely to prove troublesome, and in small gardens can be dealt with by hand picking if taken in time. When first hatched the larvæ live together in colonies, and the attacked leaves, with the entire colonies, can be picked off and destroyed before damage is done. Lead arsenate is thoroughly effective as a spray, but must not be used within a month of the time when the fruit is to be gathered. *Aphides* on the twigs may be dealt with by cutting off the stunted tips or by thoroughly washing them with nicotine-and-soap solution.

Black Currant.—The pest which as a rule attracts most attention in small gardens is the *Big Bud Mite*. The swollen buds should be picked off as soon as they can be detected, at all events before the end of February. As a further measure bushes should be pruned so that they fruit as much as possible on the one-year old wood, and this may be obtained by cutting out each winter most of the wood older than one year. Prune out the old wood as close to the ground as possible so as to obtain strong young growth.

Strawberries.—The plants sometimes suffer severely from *Strawberry Mildew*. As soon as the disease appears dust the plants with "flowers of sulphur," and repeat the treatment if necessary. A small bellows sulphurettor may be employed in small gardens, or, if it is not available, the sulphur may be shaken out of a loosely-woven bag attached to a stick. The treatment does not in any way harm the fruit for eating purposes.

(a) See Leaflet No. 195.

Spraying Machines.—There are two main types of spraying machines suitable for use in allotments or small holdings. They are

- (a) Knapsack machines. (b) Small-wheel manual machines.

Knapsack machines are the most widely used for this purpose. They are the cheapest kind of machine obtainable, and are suitable for spraying all kinds of fruit trees, potatoes and other vegetables. For large standard trees a long lance attachment can be fitted, but it is found that the pump is not sufficiently powerful to maintain the high pressure necessary to carry out this work thoroughly.

Where it is desired to spray an orchard of large standard trees, some type of small-wheel manual machine is recommended. These machines are suitable for all work for which a knapsack is used, and have powerful pumps fitted to them, so that the tops of large trees can be reached with ease. This type of machine is very much more expensive than the knapsack type, but is much more durable and useful if a considerable amount of spraying has to be done each year.

The Knapsack.—These machines, as their name implies, are carried on the back by means of shoulder straps.

They have a container holding about $3\frac{1}{2}$ gal. of fluid, and usually made of plain or tinned copper. The former is least expensive, but cannot be used for a lime-sulphur spray, for which a tinned copper machine must be used, or a machine with a container made of some chemically-resistant alloy.

Fitted to the container is a short length of hose, and attached to this is a brass lance about 3 ft. long. The nozzle is fitted to the end of the lance. For spraying large trees as previously mentioned, a bamboo lance 5 to 6 ft. long can if necessary be fitted to replace the metal one. All spraying machines are fitted with strainers.

The power for spraying is obtained by means of —

- (a) *An internal pump* which is fitted to the base of the container. Its action is similar to a pair of bellows. The valves are rubber, and when perished can easily be replaced. The present price of this type of machine is 70s.
- (b) *External pump*, which is fitted to the right hand side of the container and is of the ordinary plunger type. The valves are of metal, and are in such a position that they can easily be inspected. This type of machine also costs 70s.
- (c) *Pneumatic pressure*, which is obtained from an air pump fitted inside the container. These machines must be fitted with a pressure gauge and safety valve, and for this reason are expensive and difficult to obtain at the present time. The present price is £4 13s.

FIG. 1.—Knapsack Machine (External Pump Type) with short metal lance at work.

FIG. 2.—Adjustable Nozzle: "Mistifier Type."

FIG. 3.—Adjustable Nozzle with degorger (A); "Vermorel Type."

Small Wheel Manual Machine.—This type of machine consists of a galvanised metal container holding 12 or 18 gal., mounted on one wheel, wheel-barrow fashion. The pump is of the plunger type, fitted with an air chamber and metal valves. A pressure of 60 to 70 lb. per sq. in. can easily be maintained. There is a single or double lead of rubber hose 20 ft. long. A metal 2-ft. 6-in., or bamboo 5-ft., lance can be fitted to the hose to suit requirements. The cost is at present £13 10s. for the 12-gal. type and £14 14s. for the 18-gal. machine.

Nozzles.—These are fitted to the lance to split up the jet obtained by means of the pump into either a coarse or very fine spray to suit the requirements of the fluid which is to be applied. There are many types on the market. Those which can be adjusted to give either a coarse or a very fine spray are recommended.

Care of Spraying Machinery.—All the fluids used for the control of insects or fungi have either a strong corrosive effect on the metal or rubber used in making the machine, or else have small particles in suspension which wear away the valves and plungers rapidly.

In these circumstances, always make a point of carefully straining the spray fluid at least twice before pouring into the container. Keep all the working parts of the machine well oiled.

Always thoroughly wash out the container and pump with clean water after use.

How to Obtain Spray Chemicals.—It must be remembered that arsenate of lead and nicotine are poisonous compounds. These substances can, therefore, only be obtained from firms licensed to sell poisons. To comply with the law, every person who requires them has to sign the "poison book." The local chemist should therefore be asked to obtain a supply from a firm of wholesale horticultural sundriesmen.

The other chemicals which may be required can be obtained in a similar manner. They are also stocked in many districts by firms supplying horticultural requisites, agricultural merchants, grocers, and ironmongers.

Leaflets.—The leaflets mentioned in this article are issued by the Board, and may be obtained free of charge by writing to the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1. They give full details of the life history, diagnosis and control of the various pests to which they relate.

NOTE.—The foregoing article is also issued in the form of
Food Production Leaflet No. 39.

FURTHER OBSERVATIONS ON THE CAPSIDS WHICH ATTACK APPLES.

F. R. PETHERBRIDGE, M.A., and M. A. HUSAIN, B.A.

(*School of Agriculture, Cambridge.*)

ARTICLES which have already appeared in this *Journal* (Fryer, January, 1916; Fryer and Petherbridge, April, 1917) give accounts of observations on the life history of the Capsids which attack apples, describe the nature of the damage, and show that the injuries are due mainly to "*Plesiocoris rugicollis*," and that the only other capsid possibly doing damage is "*Orthotylus rugicollis*."

The investigation of which an account is given below was undertaken to determine the exact damage done by the different capsids in their various stages, and fuller details concerning their life histories.

The season of 1917, in which most of the observations were made, was rather an exceptional one, the early spring being very cold and followed by fairly warm weather, a state of affairs most likely to produce late and more uniform hatching. These observations were made chiefly in the Walton district near Wisbech and some were made in orchards near Cambridge.

Plants on which obvious Capsid markings were noticed were willows, apples, black and red currants and potatoes.

The different varieties of apples suffer in different ways. All those in the affected areas were attacked, but some suffer more than others. On Lady Hollendale, Worcester Pearmain, Lord Grosvenor, Lane's Prince Albert and Lord Derby the fruit was badly marked. On Grenadier, the young leaves of the early stage were badly marked and the trees were much checked, but only in cases of severe attacks was the fruit badly marked. In quick-growing varieties, like Bramley's Seedling and Early Victoria, the damage was not so severe when the fruit was ready to pick.

Species Studied.—The species of Capsids studied were the four found by Fryer, *viz.*, *Plesiocoris rugicollis*, *Orthotylus marginalis*, *Psallus ambiguus* and *Atractotomus mali*. All four were found on most of the affected trees, but the last three were also found in unaffected orchards near Cambridge. On the affected area the green bugs (*Plesiocoris rugicollis* and *Orthotylus marginalis*) were present in large numbers. The brown bug (*Psallus ambiguus*) was also fairly abundant, whilst a sprinkling of the smaller red bug (*Atractotomus mali*) was also found.

The Capsids damaging potatoes were different from the above species, the chief culprit being *Calocoris bipunctatus*, which was not found on apple trees but which damages the potato leaves in much the same way as *Plesiocoris rugicollis* does apple leaves.

Method of Investigation.—The method of determining which of these capsids caused the damage consisted in collecting specimens at their various stages from the affected trees and putting them on shoots enclosed in a muslin cover to prevent them from escaping (sleeving), or of putting them on healthy shoots kept in water in breeding cages. Some were also hatched from shoots in the laboratory and treated in a similar manner. By these methods it was found that *Plesiocoris rugicollis* was the only Capsid which caused the marking of the leaves, fruit or shoots, and that the other bugs did no damage of importance.

***Plesiocoris rugicollis*.**—The eggs of this species were found completely buried in the shoots (see Fig 1), either in the breathing pores or in the smooth bark, but we were unable to find them by a surface examination. On the bark being peeled off the eggs were discovered sticking to the underneath side of the bark, and it was then found that it was sometimes possible to see those which were laid in the breathing pores from the outside, but only on very clean shoots and with a high-power lens.

The eggs are creamy in colour, about one-eighteenth of an inch long, curled as shown in Fig. 1, and entirely buried in the stem, none of the egg being above the surface of the stem.

These eggs are laid in the shoots in June and July and remain there until the following spring, when the young bugs hatch out. In the laboratory, in 1917, the young bugs started to hatch out on 5th May, but this date is much later than usual, as Fryer records them as hatching, in 1913, before 14th April, while in 1916 a few newly-hatched bugs were found on 25th April. In 1917 the bugs continued to hatch out until 13th May. This hatching period is probably much shorter than the usual one, owing to the peculiar season.

The varieties Early Victoria, Lord Grosvenor and Lady Hollandale were in full bloom on 23rd May, much later than normal, so that the conditions which retard the hatching of the bug also appear to retard the blossoming period. A visit to Wisbech on 7th May revealed the presence of some very small newly-hatched bugs, and markings on some of the young leaves, the largest of which at this stage were about an inch long.

As soon as the young bugs hatch they stick in their beaks and begin to feed on the very young leaves, soon causing a large number of the characteristic punctures shown in Fig. 2.

The young bugs are about $\frac{1}{18}$ in. long, yellowish-green in colour, and have pink tips to their feelers. They are very active, and when disturbed run away very quickly and conceal themselves. In some varieties of apple, notably Lord Derby, the leaves remain more curled than in others, and provide more shelter for the bugs. As the time of moulting approaches the young bugs become very sluggish and do not feed, and about six days after hatching they cast their first skin. They then again begin to feed voraciously, and in about eleven days from hatching they cast their second skin. In this way they cast their skin five times, living about six days in each stage. The young bugs become bigger and greener at each successive moult.

The second and third stages are very similar to the first stage, but in the third stage very slight projections are noticeable on the second and third segments behind the head. In the fourth stage these projections or wing-pads are larger and reach to the fifth segment. In the fifth stage the bugs are about one-sixth of an inch in length and the wing-pads are still larger and reach to the seventh segment. At the sixth stage the bugs are fully winged, nearly one-fourth of an inch in length and have wings reaching well beyond the body. From the time of hatching until the bugs become adults takes about 30 days. Although the adults are capable of flying we never observed them doing so under normal conditions, but when disturbed they flew back into the tree, or into neighbouring trees, or on to the ground.

The females laid their eggs in the bark of young shoots during the latter part of June and the first half of July. By 21st July all the adults had disappeared, so that the adults are only present for about 7 weeks. The eggs remain in the shoots until the following spring, when the young bugs hatch out.

Injury to Fruit and Leaves.—Owing to the different dates of hatching several stages of the bug may be present at the same time. When the fruit set the bugs were in the third, fourth and fifth stages, and shortly after this—on 28th May—they began to injure the fruit and continued to do so until the apples were about an inch in diameter. Even when the fruit is set the bugs continue to feed on the leaves as well. Most of the damage to the fruit is done soon after it sets by the fourth and fifth stages. The adult feeds mainly on the young

Fig. 4.—*P. rugicollis*, 3rd stage, i.e., after the 2nd moult. Fig. 5.—*P. rugicollis*, 5th stage, i.e., after 4th moult. Fig. 6.—Young apples marked by *P. rugicollis*. Figs. 1, 3, 4, and 5 highly magnified.

leaves and tips of the young stems. When the young stem is punctured a brown fluid oozes out, and the stem often cracks and is in some cases killed. This is very noticeable on young trees, on which side-shooting results, and the thick growth has to be cut away in order to keep the trees a good shape.

The injury to the fruit varies considerably. In the slower-growing varieties, like Lady Hollendale and Worcester Pearmain, the damage may be enormous, as badly-marked apples do not grow to one quarter of their ordinary size and often fall off. In quicker-growing varieties, like Bramley's Seedling and Early Victoria, the fruit grows out of the injury more and, although scarred and peculiar-shaped apples may result, the reduction of the crop is not nearly so marked. In most of the varieties the punctured apples at the time of picking are russeted, owing to the scars formed by the healing of the punctures.

Other Species of Capsids.—The life history of the other three Capsids mentioned is very similar to that of *Plesiocoris rugicollis*, with the exception that they cause no damage to the fruit, leaves and shoot, and therefore have little interest for fruit-growers.

Psallus ambiguus hatches at about the same time as *P. rugicollis*, and *Orthotylus marginalis* about a fortnight later. In the adult stages these Capsids are readily distinguishable. *P. rugicollis* and *O. marginalis* are both green in colour and about one-fourth of an inch long. *P. rugicollis* is practically smooth, oval in shape, with orange-yellow edges down the outsides of both wings, and with a very small yellow collar between the head and the body. *O. marginalis* is hairy, and not oval in shape, its sides being almost parallel; it has no collar, and there is an orange spot underneath between the legs. *Psallus ambiguus* is brown in colour, but varies from a greyish-brown to a very dark-brown. It is about three-sixteenths of an inch in length. *Atractotomus mali* is reddish, and much smaller, measuring only about one-seventh of an inch in length. The lower part of its feelers are much swollen.

The young stages of these capsids are not so easily distinguished. *Atractotomus mali* is red, and therefore easily distinguished from the others. *P. rugicollis* and *Ps. ambiguus* begin to hatch at about the same time, whereas *O. marginalis* starts hatching about a fortnight later, and therefore most of the stages of the two former will be older than those of the latter—although it is possible in a season with a long hatching period that the late ones of the former will hatch at the same time as the earliest of the latter. The young stages of

P. rugicollis are green in colour, whereas those of *Ps. ambiguus* are of a dirty yellowish-green. Those of *O. marginalis* are green but may be distinguished by the presence of a very distinct orange spot in the middle of the upper side of the body. The tips of the feelers in the young stages of *P. rugicollis* are of a pinkish colour, but are not so in the other two species.

The examination of the apple orchards near Cambridge showed that, except in one case, no damage was being done to apple trees by *P. rugicollis*, and that this species was not present on the apples. The other species were all present, and *P. rugicollis* was found to be damaging black and red currants and also willows near. It is interesting to note that in the Wisbech district this Capsid attacks apples, black and red currants and willows, whereas in some orchards near Cambridge apples are not attacked by them. At Great Evesden, near Cambridge, black and red currants have been attacked for several years, and in 1917 the row of apple trees (Worcester's) next to them was attacked, while there were a few marks on other varieties near. At Histon, black currants under apple trees were badly attacked, whilst the apples were entirely free. We have also seen, both in Cambridgeshire and Norfolk, interlacing apple trees and black currants in which the black currants were attacked but not the apples.

From these observations it is difficult to say whether attacked black currants are likely to be a source of infection to the apple trees near, or how apples came to be infested in one district and not in another.

Some young bugs of the species *P. rugicollis* were taken from black currants which they were damaging and sleeved on healthy apple trees, while others were put on healthy apple shoots in cages. After a time they began to feed on the leaves and caused the characteristic markings. Some of them went through their moults and became adult on the apple. Young bugs of this species taken from apple trees and placed on black currants also reached the adult stage and caused damage similar to that done by bugs which hatched from the black currant shoots. When sleeved on plums, the bugs from the apples caused a few markings but soon died. It would seem from the above that *P. rugicollis* is capable of changing its food fairly easily, as young forms whose ancestors have lived for some years on plants other than the apple are capable of feeding and living on the apple.

NOTE.—A more detailed account of this work appears in the "*Annals of Applied Biology*," Vol. IV., No. 4.

TARRED FELT "DISCS" FOR PROTECTING CABBAGES FROM THE CABBAGE-ROOT FLY.

DR. A. D. IMMS,

Reader in Agricultural Entomology, Manchester University.

The cabbage-root fly (*Chortophila brassicæ*) is believed to be the worst enemy with which the grower of vegetables of the Brassica tribe has to contend. Numerous measures have been advocated for destroying the maggots of this insect, or for preventing the fly from depositing her eggs near the plants. With extremely few exceptions, none of the known remedies can be recommended as being sufficiently practical to merit adoption. In a recently-published bulletin, Gibson and Treherne record having experimented with no less than 48 different methods for combating root maggots. They conclude, however, with the statement that the only reliable protection, in the case of cabbages and cauliflowers, is afforded by the use of tarred felt "discs." Professor Goff, of Wisconsin, was the first to adopt the use of "discs" or protectors, and he found them reliable and efficient. His method is now extensively used in North America, where the "discs" have been frequently tested with satisfactory results. In the British Isles, and most other European countries, this method has hitherto failed to attract serious consideration. Reports on their use are extremely few, and they have not been subjected to adequate trials.

During the year 1916 a series of experiments was carried out under my direction, for the purpose of testing the value of this method under English conditions. A short account of these trials has already been published in this *Journal* for March, 1917. It may be recalled that the results achieved were extremely encouraging, and proved that the protected plants are, to a great extent, immune from attack. These results led me to the conclusion that the disc method of protection was a valuable one, and that efforts should be made to bring it into general use as speedily as possible, during the present food shortage. Arrangements were subsequently made in Manchester for the manufacture of the "discs" for the first time in this country. The maker undertook their production at his own cost and risk, and an adequate supply of "discs" was available to growers throughout the season of 1917. So far as it has been possible to estimate, about 300,000 "discs" were disposed of during that period, applications being received from growers resident in most parts of Great Britain. In all

cases full and accurate instructions were sent out along with the "discs." A number of the latter were also distributed gratis by my Department, and through the kind offices of Mr. J. C. F. Fryer, Entomologist to the Board of Agriculture and Fisheries. The condition was made that a report on their use was to be furnished in each instance at the close of the season. Applications were also received from the directors of the Station Entomologique de Paris, and the Ceylon Department of Agriculture, who were desirous of testing the method. In the case of Ceylon, the species of insect against which protection was required was not stated.

In 53 instances a correspondence was conducted with growers who were desirous of testing the discs, and it was hoped thereby to obtain independent opinions on their merits. In 13 cases (24 per cent.) the growers reported that the application of the discs had led to extremely successful results. In three instances, it was stated that cauliflowers had been grown satisfactorily by their use after successive years of failure. In 16 cases (30 per cent.) the "discs" were stated to be effective, and the growers in most instances expressed their intention of adopting the method the following year. In four cases (7 per cent.) the "discs" were considered of some value, but in each instance it was evident that the users thereof were not much impressed in their favour. In 17 cases (32 per cent.) the results were inconclusive, or were apparently unreliable, and only in four cases (7 per cent.) the "discs" were definitely stated to be of no value. As far as it has been possible to trace, the cases of failure or inconclusive results were due to one or other of the following causes :— (1) The "discs" were not applied the same day as the vegetables were planted out ; or (2) they were disturbed by high winds ; or (3) they became covered with soil after heavy rains. Various other criticisms were received, the most frequent being the trouble entailed in fixing the discs. Others complained that the "discs" did not lie flat upon the soil. In applying the "discs" to the plants it is most important to adhere to the following instructions :—

(a) When the young plants are planted out in their permanent quarters the soil should be in a fine, friable condition. This contributes in a large measure towards the discs lying flat and not suffering disturbance from high winds.

(b) It is advantageous if the soil be earthed up slightly around the plants, so as to form a flattened ridge. By this means the chances of the soil being washed on to the "discs" after heavy rains are very greatly lessened.

(c) It is very desirable that the "discs" should be applied, if possible, on the same day when the planting out is done. In warm weather the flies are especially active and are liable to attack the plants almost as soon as the transplanting is completed.

If due attention be devoted to these three points, the writer considers that there will be little cause for complaint from growers who did not achieve the success that was hoped for, when they used the "discs" for the first time. It should be borne in mind that no method of protection is perfect, and that much stronger objections can be raised against all other measures which have been advocated as a means of combating the root-fly. With a little practice, the discs can be readily fixed in position, without undue expenditure of either time or trouble. A certain amount of care is essential, but the results obtained eliminate much of the labour and expense of replacing destroyed plants.

The "discs" are now to be obtained from some of the larger seedsmen and horticulturists, while the address of the makers may be obtained on application to the writer of this article:

THE following article by Mr. A. D. Cotton, Pathological Laboratory, Royal Botanic Gardens, Kew, is reproduced, in a slightly modified and abridged form, from the *Kew Bulletin of Miscellaneous Information*, No. 1, 1918.

**Diseases of
Parsnips.**

The attention of the Board of Agriculture and Fisheries was drawn last winter to the trouble known as "Parsnip Canker." The losses of parsnip roots through this trouble proved so serious, especially in parts of Worcestershire, that it appeared advisable to make the matter the subject of special inquiry. Two visits for this purpose were paid to Evesham and district, and considerable light on the subject has been obtained. At the same time several other minor diseases of parsnips, one apparently capable of causing severe damage, were noted. In the present paper the results of the investigations on canker are recorded. (For observations on the other diseases see *Kew Bulletin*.)

That a certain number of parsnip roots in all parts of England are annually disfigured through surface-injuries on the shoulder is common knowledge, and that in some cases serious decay

follows is also well known. In certain localities this decay, which occurs in late summer and autumn, is very prevalent, and is termed "Canker" or "Rust." The name is loosely used and the trouble not easy to define; it has apparently never been specially investigated. The brownish-coloured rot shown by affected specimens is not a characteristic symptom, but is common to other types of injury, being due largely to the oxidation of substances in the mucilage present in the parsnip root. The term "Canker" as used by growers implies a more or less open wound, at first brownish-red in colour, which affects the shoulder or upper part of the root, and frequently leads in bad cases to the destruction of the entire root (see Plate I.).

Damage in 1913 Crop.—The trouble reported from Worcestershire at first seemed to be of a more definite nature, the roots having the appearance, in certain cases at all events, of a black wet-rot. The specimens were communicated by Messrs. Yates and Sons, seed merchants and growers of Evesham, in December, 1915, and throughout the investigation Messrs. Yates have most freely given valuable help and advice. A large number of bacteria and fungi were present in the decaying roots, and in certain specimens the margins of the blackened areas were permeated almost exclusively by a fungus referable to the genus *Phoma*. The fungus was easily isolated and grew freely on various media, but was not found to agree satisfactorily with any described species of that genus. It was subsequently ascertained that this black rot was a special form of decay, and that canker was not associated with any particular fungus, but arose from a surface wound, which, invaded by various kinds of micro-organisms, led more or less rapidly to the destruction of the root-tissues.

In the Evesham district it was estimated that 10 per cent. of the entire crop was lost through canker, and this, judging from figures supplied by Messrs. Yates, would amount to a loss of 370 tons of roots from seed supplied by their Evesham branch alone. In certain fields the loss was very severe; 50 per cent. of the crop in more than one case was stated to have been rendered unsaleable.

Field Observations.—Owing to the ground being frozen during the severe weather of January and February, a visit to affected areas was postponed till the beginning of March. By this date very few sound parsnips were to be found in the field in the neighbourhood of Evesham. In the localities visited the upper part of the root just visible above the soil was almost

FIG. 1. Typical example of Parnip Canker.

FIG. 2. —Illustrating formation of growth-cracks and subsequent development of Parsnip Canker; (1) horizontal cracking; (2) horizontal and vertical cracking; (3) commencement of decay; (4)–(6) further stages of decay and production of canker.

invariably undergoing decay through a white or grey wet-rot, largely bacterial, the initial injury in most cases being probably due to some other cause. No specimens of the black *Phoma* rot were seen. It was ascertained that a more or less severe form of canker occurred over a wide area around Evesham, and also in parts of Gloucestershire, whilst roots received from Somerset were almost completely destroyed through the same cause. In some cases where no rot, either wet or dry, was present a certain amount of the so-called canker was definitely attributed to the workings of Carrot Fly, and injury by this pest was found subsequently to be very considerable (see the Board's Leaflet No. 38).

At this season it was obviously too late to obtain a general insight into the nature of canker and of the black rot. A few simple tests, with regard to soil and culture for the coming season, were therefore arranged pending further examination in September, about which date canker was said to commence. These experiments included the dressing of the soil with lime, soot and sulphate of ammonia. This was carried out by several growers near Evesham, the fields being divided into four plots, the fourth plot being left as a control. Considerable improvement was expected from the use of lime, as, judging by the abundant growth of sorrel, the soil in some fields was decidedly acid. Trials at Kew were also planned as described below.

At the beginning of September another visit was paid to Evesham. The fields of seven large growers were inspected, and also the gardens of several others where parsnips were grown on a smaller scale. By this date canker had been reported by several market gardeners, and, as was subsequently discovered, was in certain localities far advanced. It was regarded as being on the whole decidedly earlier in its appearance than in previous seasons. No destructive black rot was observed, though in advanced cases a grey wet rot had commenced. Canker was noted as being more prevalent on forked or mis-shapen roots.

The effect of the various dressings employed was first examined. To form a really true estimate it would have been necessary to lift a large number of roots and have a somewhat detailed knowledge of the character of the soil and its previous history with regard to manuring. This much, however, may be said; in most fields the distribution of the canker appeared fairly uniform and to be unaffected by the dressings which had been applied. The application of sulphate of ammonia did

not apparently result in any very great increase in the growth of the parsnip or in the amount of disease. No very striking results were, however, anywhere apparent, though, on the whole, canker appeared to be distinctly worse where liming in the past had been omitted.

With regard to the physical nature of the soil and its relation to canker, in the opinion of several growers the driest lands suffer most severely. Without controverting this statement it may be mentioned that it was not corroborated during the visit. The two worst and most advanced stages of decay were found in both cases on wet heavy land (Pebworth and Sedgeberrow). A bad case was noted on light land (Fladbury). On the whole, canker appeared least prevalent on medium loam.

Animal and fungus injury were next searched for. The former was observed in some variety. The workings of the carrot fly larvae were manifest both in field and garden crops. Slug-injury was also noted, and the occasional presence of wireworms and surface caterpillars (*Agrotidae*), locally termed "leather grubs," doubtless accounted for other damage. The millipede (*Julus pulchellus*) was often abundant in the decaying parts. These animals, however, were far too few in number and too irregular in distribution to be for a moment considered as being primarily responsible for canker. Carrot fly was the most general, but it was usually sparsely distributed except in small gardens and allotments, and the characteristic tunnelings which the larvae produce, not only on the shoulder but in all parts of the outer tissue of the root, form a very definite and distinct type of injury.

Cause of Canker.—The cause of canker was more satisfactorily sought for in injuries at once noticeable in examining slightly attacked specimens—namely, the cracking of the outer skin of the root. This cracking was noted the first day, and, without ceasing to search for all indirect and subsidiary causes, was made the subject of special investigation during the remainder of the visit. The cracks were, as a rule, $\frac{1}{2}$ to 2 in. long and $\frac{1}{10}$ to $\frac{1}{2}$ in. across, and occurred either as vertical concentric slits around the top of the shoulder or ran horizontally around it at a distance of not more than about $1\frac{1}{2}$ in. below the top. Vertical cracks running down the side of the root were also present, and these appeared to be formed simultaneously with the horizontal ones to which they were, as a rule, united at their upper end. The cracks were entirely superficial, being confined to the periderm and a few layers of cortical cells.

They gaped considerably, and exposed the cortex to view as a soft, white spongy tissue.

The stages of decay from badly-cankered spots to small and sound cracks could be traced without difficulty (see Plate II.). The fresh wounds were perfectly clean (Plate II., figs. 1 and 2), but the cortical tissue within soon became attacked by animals, such as slugs and centipedes, and by various fungi and other micro-organisms. The cracks were obviously due to the expansion of the root-tissues and not to the agency of outside organisms, and were comparable to the familiar growth-cracks in carrots, but were mainly horizontal instead of vertical, and differed strikingly in being confined practically to the outer skin or rind. Subsequent observations entirely confirmed the view that canker originated from these surface lesions. That it may follow as a result of other wounds, such as carrot-fly injury, is possible and even probable, but it was obvious that a very large proportion of the trouble in Worcestershire is, primarily, due to this rupture of the periderm. The cause of crack-formation and subsequent decay of the inner tissues is discussed later.

Experiments at Kew.—Although the origin of the canker had been traced to the surface lesions described above, the organisms concerned with the actual decay had not been classified and isolated. Their distribution in the soil and their relative abundance in different localities were unknown. For this reason, the results of the soil experiments at Kew arranged the previous spring may be recorded here. Five plots of parsnips were sown in April, 1917, and were treated as follows:—

Plot A inoculated with 2 bush. of infected Evesham soil.

Plot C inoculated with cut-up diseased roots from Evesham.

Plot D inoculated with cut-up diseased roots from Somerset.

Plots B and E served as controls.

The diseased roots and soil which were obtained from Worcestershire and Somerset in March were added with a view to inoculating the soil with any organisms, parasitic, or otherwise, which might be concerned with the production of canker. The variety of parsnip sown was the same as that very largely used in Worcestershire, a broad-shouldered form of "Hollow Crown."

Preliminary examination in August and September showed the presence of many small cracks, but no marked development of canker. The plots were finally cleared on 12th November, by which date a considerable number of cankerous wounds

had developed. The results are set out in the accompanying table:—

			Per cent.
PLOT A.—Inoculated with Evesham soil (total number of plants = 96).	Sound	65	68
	Cracked	17	18
	Cankered or commencing to canker ..	14	14
PLOT B.—Control (total number of plants = 178).	Sound	103	58
	Cracked	42	23
	Cankered or commencing to canker ..	33	19
PLOT C.—Inoculated with diseased roots from Evesham (total number of plants = 76).	Sound	50	66
	Cracked	13	17
	Cankered or commencing to canker ..	13	17
PLOT D.—Inoculated with diseased roots from Somerset (total number of plants = 99).	Sound	62	63
	Cracked	22	22
	Cankered or commencing to canker ..	15	15
PLOT E.—Control (total number of plants = 168).	Sound	118	70
	Cracked	26	15
	Cankered or commencing to canker ..	24	15

From the above it will be seen that from 15-23 per cent. of the cracking occurred in all plots, and from 14-17 per cent. of canker. The figures for the latter are high, but except in plot C the canker was in an early stage, and the roots were marketable and not appreciably damaged. In plot C eight roots had badly decayed, but from the presence of equally severe injury noted in some neighbouring plots (not included in the experiment) this cannot, without further proof, be attributed to the effect of the inoculation with diseased roots. It may be due to early cracking and early commencement of decay. The experiment as a whole tends to show that inoculation with diseased material had no effect, since of the controls one (B) showed the maximum amount both of cracking and of canker, and the other (E) almost the minimum.*

In addition to the above, efforts were made by means of direct observation of roots in the Kew plots to follow the course of development of the cracks and the subsequent decay. The results were not conclusive—a fact which may be partly due to the observations being made late in the season, namely, in September, after the return from Worcestershire. Nine growth-cracks on roots in plot B were carefully examined and

* Experiments carried out by Messrs. Yates at Evesham for testing the effect of manures showed a distinctly larger percentage of canker than at Kew. The use of lime proved highly beneficial both with regard to size of roots and reduction of canker. The use of manures alone, such as Peruvian guano, sulphate of ammonia and superphosphate of lime, was not successful in mitigating the disease.

measured, the roots being left *in situ*, the soil merely scraped away for purposes of inspection, and replaced at once. The weather was somewhat dry for the first ten days after marking. After two weeks the plots were examined when but little extension of the cracks and no decay had taken place. Two weeks later, after considerable rain, a little decay had commenced and some new cracks had appeared. After another fortnight, *i.e.*, six weeks after marking, the roots were lifted and examined, with the following results :—Three slits had not increased in size and remained sound, 3 had distinctly increased in size yet remained sound, 3 had increased in size and developed cankerous wounds. Some 6 or 7 new cracks had developed, all of which remained sound.

In another set of roots on the same plot a series of shallow vertical cuts on the top of the crown resembling growth-cracks were made with a knife. Examined 6 weeks later, four remained sound and two developed into a cankerous wound.

A similar experiment was performed on plot C (infected soil) with the addition of 12 horizontal cuts on the side of the root. All these cuts, however, remained sound. It was noted that an injured surface attracted slugs, slug-injury being obvious both in growth-cracks and artificial cuts.

Summing up the Kew experiments, it may be said (1) that growth-cracks occurred at Kew as in Worcestershire, but they were decidedly smaller in size and later in developing ; (2) that canker followed in a few cases as a result of these or other injuries ; and (3) that canker was found to be no more frequent in the plots inoculated with Evesham soil or with diseased roots from Evesham than in the ordinary Kew soil. The less extensive cracking may perhaps be accounted for by the small size of the roots. This was due to the seed being sown late (mid-April) and the soil being a heavy compact silt which had not been manured for two years.

Anatomical Considerations.—It is obvious to the naked eye that the cortical tissue exposed to the air as a result of cracking does not heal over. Anatomical examination shows, however, that an attempt is made on the part of the plant to protect itself, inasmuch as the outer and side walls of the exposed cells become suberised. A few cell-divisions also take place, but there is no trace of a definite phellogen or of a layer of wound-cork. This protection is quite inadequate to keep out micro-organisms, the inter-cellular spaces and cracks or fissures due to drying providing ample means of entry. The soft

parenchymatous tissues are, moreover, specially attractive to slugs, an immense amount of slug-injury being noticeable if large gaping slits are made with a knife. It is, therefore, not surprising that decay sets in and canker follows, and the cause may be said to be entirely due to the inability of the parsnip to form a protecting layer of wound-cork. The deep open clefts which occur in the roots of swedes, carrots, mangolds, and turnip become protected on their surfaces by a thin cork layer. No cork layer is formed when such deep cuts are made artificially in the parsnip. It would appear, therefore, that the hindrance to cork-formation is not due to the different method of cracking, but to some physiological peculiarity of the parsnip root.

The Causes of Cracking and Remedies.—The formation of growth-cracks is a phenomenon familiar enough to gardeners, and is of common occurrence not only in root crops, but in fruits, such as apple, pear, and cucumber. In the pulpy fruits of plum, cherry, and tomato a cracking of the skin is also frequent, and in this case, as in the parsnip, decay results.

Cracking is brought about by an unequal growth in the structures concerned; the inner tissues grow more rapidly, and ultimately rupture the outer layers. In the case of the pulpy fruits mentioned, cracking may be partly due to excessive turgidity of the inner cells. In either case it is, as a rule, due to the effect of an abundant supply of water at the root after a dry period, but at times it appears to be merely the result of rapid growth, when the expansion of the surface tissues does not keep pace with that of the inner. The effect of hot sun and dry conditions, especially, if there is not a copious supply of water at the root, is to ripen growth, and this entails, amongst other things, loss of elasticity in the cell-walls and decrease of the power of cell-division. Dry conditions, whether in the case of fruits or roots, are felt first at the surface, and hence surface tissues are more subject to premature ripening. If late summer rains stimulate new growth, the outer, partly ripened tissues respond more slowly, and if the pressure from within be excessive they are liable to become ruptured.

The above considerations apply to the parsnip and explain to a certain extent the cause of cracking. It is obvious that the very wet September of 1916 following the warm, dry August was conducive to late and rapid growth, which would, for the reasons given, lead to extensive cracking of the surface tissues of the root, and an unusual abundance of canker. In 1917 canker may have been increased by the wet August.

From information collected from various growers cracking was general in 1916 in parsnip-growing localities, though the losses elsewhere were much less serious than at Evesham. One may inquire therefore as to the presence of special conditions at Evesham, which might tend to aggravate the trouble.

On the cultural side there is evidence of several contributory factors. In order to obtain a heavy crop the seed is sown in February, at an earlier date than formerly. By this method the roots reach a large size by July and August, and there is probably a tendency to premature ripening. This theory receives support from the fact that several growers maintain that liability to canker is lessened by late sowing. The soil itself may be too rich. Though fertilisers are never applied directly to the crop, the Evesham soil is well known often to be highly manured, and given favourable weather conditions this would lead to excessively rapid growth, and consequently risk of much cracking. A highly-fed plant, moreover, would decay rapidly. In addition there is evidence, in the case of certain growers at all events, that parsnips are grown on the same land for two years in succession and that a proper rotation is not given. The effect of the latter course is not only unfavourable for parsnip growth, but tends to stock the soil to the full with the particular organisms, both animal and vegetable, concerned in their decay, and hence if cracking occurs the parsnip might be expected to be rapidly destroyed. Lastly, liming has been neglected. Experiments carried out by Messrs. Yates in 1917 show a decided improvement where lime was applied.

Yet another cause of the severity of the canker attack may lie in the nature of the variety of parsnip grown. As already mentioned breeders aim at a small core and ample flesh, an ideal well seen in the Evesham parsnip root, which is noted for its bulky, fleshy top. Such a soft mass of parenchymatous tissue would probably be easily stimulated to extensive growth after rainy periods during the summer months and to rapid expansion of the inner tissues. The breeders may have exceeded the limits in that direction and produced a parsnip particularly subject to a physiological defect. As evidence in favour of this view it may be mentioned that in allotments in Worcester, though the long slender parsnip such as "Student" showed rupturing of the rind and a certain amount of canker, these were not so extensive as in the Evesham parsnip.

Preventive Treatment.—In order to reduce the amount of surface-cracking and canker the following treatment, based on the above conclusions, may be recommended :—

1. Too rich a soil must be avoided.
2. Late sowing should be adopted. Such observations as it has been possible to make in 1917 tend to confirm growers' statements that plants from seed sown at the end of April or beginning of May suffer much less than those from seed sown in February.
3. Liming must not be neglected. As well as improving the tilth, lime acts by liberating reserves of nitrogen and potash, and its effect on the parsnip is seen in the improved quality of the crop both in size of roots and decrease in the amount of decay.
4. A dressing of salt has been found very effective by some growers. On heavy soils 5 cwt. per acre should be applied, and on light soils up to 10 cwt. per acre may be used. The salt may act by liberating a certain amount of potash from the soil, and one of the most marked effects of potash is to retard maturation and to enable the plant to continue its vegetative growth. It is possible that this effect may extend to the phellogen (rind-producing layer) and consequently render it less liable to rupture. For the same reason potash manures should prove beneficial.
5. A proper rotation should be given, and parsnips must never be grown for two years in succession on the same land.

Summary.—The canker of parsnip or the decay of the upper part of the root in late summer and autumn is a disease well known to growers, but one which has apparently never been investigated. In certain districts it has recently been on the increase and is responsible for serious losses. It is shown to be due primarily to a physiological phenomenon which causes the surface tissues to become ruptured or cracked, and not to the invasion of a fungus parasite. Decay also follows as a result of a severe injury caused by carrot fly, slugs and other animals, but in the areas investigated such injury was scarce. Cracking takes place during the growing season especially if rains follow a dry period, the portion involved being the skin, *i.e.*, the periderm and the outermost layers of the cortex. The cracks, which for the most part run horizontally around the upper part of the root but also in a vertical direction,

are from $\frac{1}{2}$ to 2 in. long and gape open, exposing the soft inner tissues.

The "canker" or decay which follows is shown to be the result of the inability of the parsnip to form a layer of wound cork. Though the outer walls of the exposed cortical cell become suberised and few cell-divisions occur no definite phellogen is formed, and the growth-cracks are not protected as they are in the case of carrots, swedes, and other fleshy roots. The suberisation of the outer walls is insufficient to exclude micro-organisms, which enter, probably by means of inter-cellular spaces and fissures due to drying, and more or less rapidly destroy the tissues of the root. Though canker is worse in some localities than others it appears to occur in all districts if rupturing of the skin takes place. No one micro-organism specially connected with the decay has been isolated.

The conditions leading to crack-formation suggests that whilst such cracks are due to an unequal rate of growth, the inner tissues growing more rapidly than the outer, and are governed very largely by weather-conditions, their formation may be favoured by certain methods of culture, namely, over-manuring, neglect of liming and by early sowing (inducing premature ripening). The variety of parsnip grown may also be partly responsible. a form of high quality, with bulky top, abundant flesh, and small core, being very largely cultivated in the worst infected areas.

Control measures consist in rectifying the faulty methods of culture alluded to, and the use of potash and common salt with a view to retarding maturation.

THE Report* for the year 1917 on the Proceedings of the Board under the Act relating to the provision of experimental Small Holding Colonies for the Land Settlement of ex-Service men states that under the Act which came into force on 23rd August, 1916, the Board have now either acquired or agreed to acquire all the land which they are authorised to hold under the Act (6,000 acres in all), and the selection of sites for the Colonies involved a very considerable amount of work. A number of estates were inspected by the Board's officers and

* Annual Report of Proceedings under the Small Holding Colonies Act, 1916, for the year 1917: *Board of Agriculture and Fisheries.*

reported upon as being unsuitable for various reasons; and those finally selected have only been acquired after careful consideration of all the factors likely to affect the success of the Colonies, including soil and situation, cost of equipment, proximity to markets and the prospect of financial return. In this connection, it may be pointed out that, under existing financial conditions, the Board have been considerably handicapped by the difficulty of establishing experimental colonies upon a sound economic basis, as not only is the cost of building some 70 per cent. in excess of pre-war cost, but the rate of interest for loans for small holding purposes now stands at $5\frac{1}{2}$ per cent., and it seems probable that any schemes which may be initiated within the next few years for the provision of Small Holding Colonies must be subject to the operation of these drawbacks.

Tenure.—The Departmental Committee on Land Settlement for Soldiers and Sailors considered (Part I. of their Final Report, page 8, paragraph 26), that, as a general rule, it would be necessary that land acquired for Farm Colonies should be purchased, but that if land could be acquired on long lease on satisfactory terms, advantage should be taken of such facilities, owing to the great reduction which would be effected in the capital cost incurred in establishing the settlements. In acquiring land for their Colonies, the Board have proceeded in accordance with the views of the Committee, and they have taken two estates in England on long lease from the Crown. It has been found necessary, however, to purchase the land for the third English Colony and also that for the Welsh Colony.

Estates Acquired.—(i.) *Patrington Crown Colony.*—The first estate was acquired by the Board in the autumn of 1916, and it comprises an area of 2,363 acres, situated near Patrington in the East Riding of Yorkshire, about 15 miles from Hull. This land has been hired from the Crown on a lease for 99 years at a rental of £3,277 per annum, and it was originally intended for a Colony of the mixed farming type on which the average size of the holdings would be about 35 acres. The Board have since decided, with Treasury sanction, in the interest of the settlers, that this estate shall be worked for a time on a profit-sharing basis, instead of being divided up at once into small holdings, as it seems probable that the land can be worked to greater advantage on that basis until it has been ascertained, by practical experience, to what extent the heavy warp land is adapted for the intensive crops required on small holdings.

Possession of this estate was obtained on 6th April, 1917, and Mr. R. N. Dowling, formerly Agricultural Organiser to the Lindsey County Council, was appointed Director of the Colony on the 1st January, 1917, and, after the necessary preliminary work, took up his residence at Patrington on the 9th May, 1917. The estate is being farmed as a whole, and, as but few prospective settlers have arrived at the Colony, the Director has to depend mainly on local labour for cultivating the land, and on the services of soldiers temporarily released from the Army. It is anticipated, however, that about 60 settlers will be placed eventually on the property.

As regards equipment, 22 pairs of cottages are in course of erection by the Housing Organisation Society, who were appointed to act as agents on behalf of the Board. About 15 pairs of cottages have been completed, leaving 8 pairs still to be erected. In addition, various alterations and repairs to the existing buildings have been effected by the Society.

(ii.) *Crown Estate, Holbeach Marsh*.—The Board have also acquired from the Crown on a lease of 99 years, 1,000 acres of land on the Crown Estate, Holbeach Marsh, in the Holland Division of Lincolnshire, at a rental of £1,623 per annum.

This estate is intended for the market-gardening type of Colony, for which it is well adapted, both in respect of soil and situation. It is proposed to divide the land into holdings of about 10 acres. Suitable cottages and buildings are being provided for each holding, and the Colony should accommodate about 80 settlers. Only two holdings have so far been taken up, otherwise the estate is being farmed as a whole.

Possession of this estate was obtained on 11th October last, but by arrangement with the quitting tenants, building operations were commenced at the end of April, 1917. In this case, the contract for the erection of the cottages was put out to competitive tender.

(iii.) *Heath Hill Estate (Salop)*.—This property comprises about 1,150 acres and formed part of the Duke of Sutherland's Lilleshall Estate; it has recently been purchased by the Board for the sum of £40,000. It is estimated that this land will provide for the requirements of some 40 small holders, and that the holdings will be of the dairying and market gardening type. The Board were to obtain possession of the estate at Lady Day, 1918, and plans for its development have not yet been completed.

It is proposed to appoint as Director of the Colony Mr. Henry Henshaw, who was for 10 years, 1900-1910, Manager of

the Cambridge University Experimental Farm, and has since 1915 filled the post of Agricultural Adviser and Pedigree Live Stock Agent to Messrs. Chivers and Sons, Limited, of Histon, Cambs.

(iv.) *Pembrey, Carmarthen*.—After consultation with a Committee appointed by the Welsh Agricultural Council, the Board have agreed, subject to the completion of a formal contract, to purchase an estate of 1,345 acres at Pembrey for the sum of £30,000 from Lord Ashburnham, as a site for the Welsh Colony. This Colony, possession of which is expected to be obtained at Michaelmas next, will probably provide for about 60 settlers.

Selection of Applicants.—A considerable degree of misconception has been found to exist in regard to the scope of the schemes which the Board are called upon to administer under the Act, and it may be desirable to point out that, while the Board hope to be able to find employment for a certain number of disabled men, yet the latter can form only a very small proportion of the ultimate settlers, as the Colonies were not intended to make provision for disabled men as such, but to ascertain by actual experiment how far small holdings grouped on the Colony system on the lines recommended in the Report of the Departmental Committee can be successfully organised. The claims of disabled men will always receive sympathetic consideration, but the first consideration in the selection of applicants must be their prospective capacity for earning a living on the land.

The Board have prepared a special form of application, which is sent out to applicants. On the return of the completed application form it is registered, and the Board arrange to interview the applicants at some convenient centre with a view to ascertaining their suitability for becoming small holders. In cases where applicants are required to make a journey for the purpose, the Board have been authorised by the Treasury to pay 3rd-class railway fare.

Where the applicants seem likely to prove suitable and have received their discharge from the Army, arrangements are made for them to commence work at an early date on one of the Colonies for which they have indicated a preference. As a rule an applicant, after acceptance, will be required to work for wages on the Colony for a year before he is finally accepted and allotted a holding.

Advance of Capital.—Inquiries are frequently made by applicants as to whether advances of capital are made by the State to enable them to take up holdings under the scheme; but the

Board have no power to make advances for the purpose, and the suggestion was expressly negatived by the Departmental Committee on Land Settlement for Soldiers and Sailors, who found themselves unable to recommend such a proposal, to which they felt there were serious objections.

It is satisfactory, however, to note that a considerable number of applicants possess a certain amount of capital, which in some cases may be regarded as being adequate. Out of 178 cases dealt with by the Board it was found that while 54 applicants possessed capital of not more than £50, 42 had from £50 to £100, 26 from £100 to £200, 13 from £200 to £400, while 43 (or less than one-fourth) possessed practically no capital at all.

A certain number of applicants have indicated their desire to purchase holdings on the Colonies. This is obviously impossible where, as at Patrington and Holbeach the Board hold the land on lease ; but where the Board own the freehold of the estate, they have power, subject to Treasury sanction, and subject also to the provisions of Section 12 of the Small Holdings and Allotments Act, 1908, to dispose of it to the occupiers, who may pay for it by periodical instalments spread over a term of years.

Cottage Accommodation.—With regard to the erection of cottages, as to which many enquiries have been received, it is intended that they should be built on or near to the land which is to be occupied with them, and, for the sake of economy, the cottages are being built to one plan ; but the outbuildings have not yet been commenced, as it is anticipated that many of the military hutments may be utilised for the purpose, and a considerable saving thereby effected in the rent that will have to be charged to the tenants.

Type of Colonies.—It was originally the intention of the Board to establish Colonies devoted to fruit and market gardening, dairying and mixed farming respectively, and to cut up the estates acquired into small holdings as soon as applicants possessed of the necessary capital and experience were forthcoming, but the Board have since had reason to modify their plans and they have decided (subject to Treasury sanction) that the Patrington Colony, at any rate, shall be worked for a time as one farm, on a profit-sharing basis. Subject to this reservation, the Board have kept in mind the desirability of establishing Colonies of the three types referred to.

MARKET reports show no sign of any increase in the supplies of feeding stuffs in general, but there are indications that a few articles are reaching the markets in rather larger quantities. American linseed cake, Egyptian cotton cake, maize gluten feed, Chinese beans and millers' offals are among these articles and appear to be fairly plentiful, especially in the west of England.

**Notes on Feeding
Stuffs for May:**

*From the
Animal Nutrition
Institute, Cambridge
University.*

As regards prices, readers should study the Cattle Feeding Stuffs (Maximum Prices) Order of 7th February, 1918, which was reprinted in the last number of this *Journal*, p. 1474. This Order fixes the price of practically every kind of concentrated feeding stuff.

The Rationing of Live Stock Order which, it is understood, the Ministry of Food are about to issue, has not yet* appeared, but advance Press notices of the Order indicate that the system of Priority Orders, which has been at work for some time for milch cows, is now being extended to certain other classes of livestock, namely, horses maintained and used for agricultural purposes only, calves under six months old, breeding sows, store pigs, and milch goats. Anyone possessing animals of any of these classes can now obtain a Priority Order, which will entitle him to buy feeding stuffs in strictly rationed quantities.

To obtain such an Order, application should be made to the Area Live Stock Commissioner for the district. A list of the names and addresses of the Area Live Stock Commissioners appeared on p. 1471 of the March issue of this *Journal*.

Although the Priority Order entitles the holder to buy feeding stuffs up to a certain limit, it does not always ensure that a sufficient supply of the desired foodstuffs will be available. Holders of Orders may have to be content with feeding stuffs of some other kind than the kind ordered. It may even happen that it is impossible to purchase the requisite amount of feeding stuff of any kind. In this case holders of Priority Orders should apply to the Secretary of the Feeding Stuffs Committee, whose address can be obtained by application to the Area Live Stock Commissioner.

The attention of livestock owners is drawn to the serious shortage of coarse fodders, and it is hoped that all feeders will exercise the strictest economy with reference to the hay and straw in their possession. As feeders are doubtless aware, most stacks of hay and straw are ear-marked for Army purposes.

* April 18th.

Arrangements have been made, however, for the release for civilian use of such supplies of hay and straw as are not required by the Army, and trade nominees have been appointed to deal with these supplies. Any one requiring hay or straw should write to the District Purchasing Officer of Supplies for his county, who will doubtless put him in touch with the trade nominees who have supplies available.

Such supplies, however, are primarily intended for town and urban district requirements, since all farmers are allowed to retain such of their hay and straw as they require for their own stock. It cannot be too strongly urged that farmers should estimate their requirements accurately, in order to prevent any possible shortage occurring with regard to their own supplies, as it may prove almost impossible to replace at short notice any deficiency in this respect.

Horses.—According to the advance Press notices of the Rationing of Live Stock Order, owners of horses maintained and used for agricultural purposes may obtain Priority Orders, which will entitle them to buy enough concentrated feeding stuffs to provide, with their own home-grown foods, a ration of 10 lb. per day per horse. This ration is a maximum one and it should be possible to save on it as soon as the grass comes. Every owner of horses should take steps to ensure that his men do not exceed the ration.

Milking Cows.—The working of Priority Certificates for milking cows is now well understood. During this month, cows generally will be turned out to grass, and it should not be necessary to give them any concentrated food, except, perhaps, a small allowance of some astringent food, such as cotton cake, to prevent them scouring for the first week or so until they get used to a grass diet.

Other Cattle and Sheep.—Except in the case of young calves, for which a Priority Order for $\frac{1}{2}$ lb. per head per day of concentrated food may be obtained, no food should be required except grass.

Pigs.—The feeding of pigs was fully discussed in last month's notes. Since then, according to the Press notice issued by the Ministry of Food, pig keepers are entitled to Priority Orders for breeding sows at the rate of 4 lb. of meal per day, and for store pigs at the rate of $1\frac{1}{2}$ lb. per day. These amounts will, of course, not suffice for fattening, but they should enable pig keepers to produce large quantities of strong store pigs suitable for feeding on grass and other green stuff or refuse materials of various kinds.

The Ministry of Food have also announced in the Press that young pigs may be sold as stores up to 80 lb. live weight ; that is to say, at market price and not by live weight. The Ministry have further stated that no pig may be sold for slaughter weighing less than 112 lb. live weight and that the price of pigs for slaughter has been substantially increased. In addition, the President of the Board of Agriculture has appointed a Director of Pig Production, from whom full information may be obtained as to methods of feeding pigs in war time.

Dependence on Home Supplies of Manure.—Owing to the exigencies of the War farmers may be thrown more and more on their own resources for fertilising the land, and all possible care should be taken of home supplies of manure, which are really considerable in amount, though they have been somewhat neglected in the past in consequence of the great supplies of artificial manures available. The farmer is now in a somewhat similar position to that of his predecessor in the 'forties and 'fifties of the last century, who had to farm, and did farm, without drawing supplies from all over the world, and who had none of the good implements and organisation of modern times to help him.

Avoid all Waste of Farmyard Manure.—The greatest possible care must be taken of farmyard manure, and especially of the urine, which is its most valuable constituent. On no account should any liquid manure be allowed to run to waste ; the urine should be completely absorbed by litter, and if there is not enough straw available, bracken or some other substitute should be used.

The manure should not be exposed much to rain ; black liquid running away from a manure heap is a sure sign of wastage. The liquid itself might be collected, but this would not completely repair the damage because the loss brought about by rain is only partially due to drainage ; the more serious part is not shown in this way.

As far as possible summer storage of manure should be avoided, as it is during this period that the greatest losses arise. In peace time a certain amount of summer storage was inevitable, because on some farms the acreage under roots and

potatoes was insufficient to absorb all the manure produced. The Rothamsted experiments show that none of the methods at present in use can be relied upon to prevent loss in summer. Compacting the heap is satisfactory in winter and in the early days of warm weather because it delays the setting in of the decomposition processes, but it affords no lasting protection against them, and once they start in summer they go as far in the compact heap as in the loose heap. In two of the trial heaps of bullock manure kept over the summer at Rothamsted the losses were :—

	<i>Compact Heap.</i>		<i>Loose Heap.</i>
	<i>Per cent.</i>		<i>Per cent.</i>
Of Dry Matter...	47.5	45
Of Nitrogen ...	42	32

The proper way of avoiding the loss is to have a sufficient acreage of roots and potatoes to take the whole of the manure available till the end of the spring, so as to leave only the daily production to accumulate during the summer.

Composts.—Farmers might well turn their attention to the possibilities of making compost heaps. The art was well known to agriculturists during the 'fifties and 'sixties of the past century, and in the old days, before large quantities of artificial fertilisers were available, farmers and gardeners made great use of composts. Indeed, in the *Gardeners' Chronicle* for 1845, Mr. Errington describes no fewer than 20 different composts for garden purposes, and explains their uses. He attributes some of the most marked of the then recent advances in horticulture to a better understanding of the use of composts.

Mr. Hannam, of Kirk Deighton, Wetherby, writing in Morton's *Cyclopædia of Agriculture* in 1855, describes the best method known to him of making composts on the farm. He describes three kinds—Farmyard Manure composts, Lime composts and Earth composts. *The Farmyard Manure composts* are made by mixing sods, turf, leaves, heath, moss, rushes, weeds, clippings, etc. (but not animal refuse), with farmyard manure in alternate layers each about 1 ft. in thickness, and covering the whole with a coating of earth. After the mass had undergone considerable decomposition it was turned and roughly mixed, and a covering of ashes, charcoal or earth again spread over it. Liquid manure was also added with advantage.

Lime composts were made by mixing lime with peat, sawdust, bark, roots of couch grass, hedge clippings, ditch scourings,

road scrapings, weeds from fallows, sods, etc., the mixture being as uniform as possible. The heap was turned two or three times before use, and was ready in two or three months.

Earth composts were made by mixing soil with animal matter, waste fish, blubber, wool waste, shoddy, etc., and treating the heap as before. The resulting fine earth was drilled with the seed so that the young plant started in the artificial soil. The results obtained from a well-made compost were said to be as good as from farmyard manure.

Manuring of Barley.—When barley is grown after roots fed off it is often improved by 2 cwt. of superphosphate per acre. If no cake has been fed, or if the roots have been drawn off, a nitrogenous dressing will be needed, such as $\frac{3}{4}$ cwt. of sulphate of ammonia or 3 cwt. of rape cake. There is no substantial evidence for supposing that a nitrogenous dressing in this amount injures the quality; season is far more potent than manuring in this direction. In the Yorkshire experiments 1 cwt. of sulphate of ammonia gave an additional 5 bush. of grain, while the phosphate gave an additional 2 bush.

If the land has been well sheeped prior to barley, the phosphatic dressing may be increased, and on light soils 2 cwt. of salt may sometimes be applied with advantage, especially if "seeds" are to be sown in the barley; salt and phosphates both help to keep the crop standing up and thus avoid "lodging" and consequent smothering of the young plants of the clover mixture. Salt does not always act well, however; it proved ineffective in the Norfolk experiments.

Manuring of Flax.—Flax may be grown primarily for the sake of the fibre as in Ireland, or for the seed as in certain parts of England, and the manurial treatment differs according to the purpose in view.

For Fibre Production.—An extended series of experiments has been made in Ireland, especially in the north, where a considerable quantity of flax is grown. These show the great value of potassic fertilisers, kainit and muriate on the whole proving better than sulphate. In some seasons a dressing of nitrogenous fertiliser—rape meal or sulphate of ammonia—was advantageous, but not always. Phosphates encouraged the weeds more than the flax, and therefore are not recommended. Pending further investigations the Irish Department recommend the following dressing for fibre production: 5 cwt. of kainit or $1\frac{1}{4}$ cwt. of muriate of potash per acre, or their equivalents, applied during winter, or at the time of sowing.

Seed Production.—For seed production, on the other hand, there is no evidence of any special need for potash, nor of any harm done by phosphates—indeed, rather the contrary. Generally speaking a farmer would probably be safe in treating flax grown for seed as he would treat barley.

Treatment of Grass Land.—In view of the shortage of fertilisers it may not be possible for farmers to use as much on their grass land as they would like. It may be pointed out, however, that considerable increases in grass crops, both on pasture and on hay land, can be obtained by suitable cultivations, especially by going over the grass early in the year with a toothed harrow so as to break up the surface and allow better aeration of the roots. On pasture land a good deal can be done by collecting and spreading the *fæces* as is done in Northamptonshire; this not only tends to keep the herbage uniform by preventing excessive accumulations of nitrogenous manure near hedges, gates, etc., but it reduces the loss which inevitably occurs as soon as large amounts of *fæces* are assembled together. Any slag that can be obtained, even of low grade, should be put on.

Waste Lime Products.—Further satisfactory samples of waste lime products continue to be sent to the Food Production Department. One of the latest is from the Forest of Dean, and this ought to be of considerable local interest in view of the fact that many of the soils of the district need lime.

THE object of this article is to direct attention to the value of buckwheat as an auxiliary grain-crop, peculiarly suited to the circumstances of the present time.

The Cultivation of Buckwheat.

Advantages of the Crop.—Although strictly not a cereal, buckwheat closely resembles the cereals in composition, and may be largely used to replace these for general feeding purposes.

It will grow on sandy, gravelly soils which are too precarious for other crops, and its cultivation is simple and inexpensive.

It requires only from 12 to 14 weeks to mature and can therefore be sown late; indeed, to avoid damage by frost, to which it is very liable, it should not be sown before the middle of May, and the end of June is not too late in a favourable year. It can, therefore, take the place of crops which have failed or which could not be sown in due season.

It has been grown with success on land which would ordinarily have been bare-fallowed, and for this reason is specially to be recommended at the present time; it is an excellent smother crop, and leaves the land in fine, friable condition for autumn corn or other crops.

Though it is a seed-bearing crop it belongs to an order of plants which differ in soil and food requirements from the cereals, and it may, therefore, follow or precede these without injury to either crop.

Varieties.—There are three main varieties in cultivation, but the common type (*Polygonum Fagopyrum*. L.) is the only one in general use.

Soil and Climate.—The crop will thrive on a wide range of soils, but is best suited to warm, well-drained sandy loams. On the richer classes of soils, such as those of the Fen districts, it grows luxuriantly, but it cannot, from an economic point of view, compete with the cereals under such conditions, and only when such crops have failed or cannot be sown should buckwheat take their place. Its special value as a grain producer lies in the fact that it will produce an appreciable crop on the poorest natural description of soils, or on other light soils, which have been allowed to sink into poor condition, but on cold, wet lands it is not very reliable.

The plant is very sensitive to low temperatures and may be destroyed in a single night of frost, whether at the beginning or end of its period of growth.

It is chiefly cultivated in the Fen districts of Norfolk and Cambridge, and on the poor, thin soils found in East Anglia.

Preparation of the Land.—No great amount of preparation is required. But the finer the tilth, the better will be the results, as the roots spread chiefly in the surface soil, and are not capable of dealing with hard clods. On the lighter soils a single ploughing, followed by harrowing and rolling, is generally all that is required.

Manures are rarely applied directly to buckwheat; what remains from previous applications is generally sufficient. On poor, sandy soil, however, farmyard manure, if available, may be applied together with a dressing of superphosphate.

Sowing the Seed.—The seed should not be sown until the end of May or beginning of June. It should be of good weight (about 50 lb. per bush.) and of good germinating power. The seed may be drilled in the same way as corn at the rate of

about 2 bush. per acre, but many farmers prefer to sow in rows, 14 in. apart; in this case from 1 to $1\frac{1}{2}$ bush. per acre are sufficient. For sowing broad-cast, up to 3 bush. per acre will be required.

As little moisture is necessary for germination, it is a mistake to bury the seed too deeply, $\frac{1}{2}$ in. to $\frac{3}{4}$ in. being sufficient. Provided that the land has been well cleaned before sowing, no further cultivation will be required.

Harvesting.—Ripeness is indicated by the general browning of the crop, but even then flowers, a succession of which is produced right into late autumn, will be noticeable on some of the branches. The best time to cut, therefore, is when the majority of the seeds are formed and before the earliest have fallen.

The crop is harvested in various ways, but the usual method is to cut with a scythe or reaper and leave to dry for a few days before tying up and shocking with the weathered side inmost. The preliminary drying before "shocking" is necessary on account of the sappy nature of the straw.

After thorough "winning" in the field the crop is carted and stacked. In stacking it is usual to make the stacks quite small and to put in here and there a layer of wheat-straw to take up the surplus moisture.

Yield.—The yield of grain varies greatly, the average being about 3 qr. per acre; on poor soils in bad seasons it may be less, while on richer land in a good year it may amount to 6 qr. per acre.

The weight per qr. as sold in the local markets is 28 stones (392 lb.)

Uses of Buckwheat.—(1) *Grain.*—In many parts of the Continent buckwheat bread still forms the staple diet of the poorer classes, while in the United States large quantities are used for human food, in the form of buckwheat groats, etc. The buckwheat is ground and the outer black hull separated.

In this country the crop is grown chiefly for the purpose of feeding game and poultry. As a feeding stuff, the buckwheat grain is characterised by a somewhat high fibre content, otherwise it is roughly intermediate in composition between barley and oats.

Analyses.

	Water.	Albuminoids.	Fat.	Carbohydrates.	Fibre.
Buckwheat..	13 ..	11 ..	2 ..	60 ..	12
Barley ..	14 ..	10 ..	2 ..	67 ..	5
Oats ..	13 ..	12 ..	6 ..	55 ..	10

When cracked or ground and mixed in small quantity with other foods, buckwheat may be fed with good results to horses, cows or pigs.

(2) *Straw*.—Buckwheat straw is seldom used for feeding purposes, but on occasions when other fodder is scarce, it may be chopped and mixed with other material and fed to cattle and sheep with advantage. As litter the straw does not last well, but it makes good bedding for cows. As it is rich in mineral matter and rots quickly, it also makes good manure.

This article is also issued separately as Food Production Leaflet No. 42.

THE attention of allotment-holders, gardeners and small cultivators generally was last month drawn by the Food Production Department to the value of the Jerusalem artichoke, both for purposes of human food and for feeding to pigs.

Recent investigations by the Royal Society Food (War) Committee show that when eaten in moderation the artichoke is an excellent human food, and that its food value, as measured in calories, is superior to that of the potato. The composition of artichokes and of potatoes is as follows :—

		<i>Water.</i>		<i>Proteins.</i>		<i>Total Carbohydrates.</i>		<i>Calories Per lb.</i>
Artichokes	..	79.5	..	2.6	..	16.7	..	365
Potatoes	..	75.5	..	1.8	..	14.7	..	310

The artichoke, moreover, yields large crops. An average yield from field cultivation is about 10 to 12 tons, but in gardens and allotments when the soil is rich it should be considerably higher. Estimates of yield obtained by the Royal Society Food (War) Committee give figures as high as 20 tons per acre on garden ground.

Other advantages possessed by the Jerusalem artichoke are that it is not subject to disease, and will grow in almost any soil and situation provided that there is an abundance of light and air. It succeeds best on a deep, friable, sandy loam.

For planting, medium-sized tubers should be chosen, or larger tubers may be cut into pieces each with two or three eyes. The white tubered varieties are generally preferred to the pink as they are of a better shape.

In the south, planting should be done during March or the beginning of April, but in late districts and in the north

planting may be continued until the end of April. The tubers may be planted in shallow trenches or dibbled 4 to 5 in. deep in soil which has been well worked. The usual distances at which to plant are 3 ft. between the rows and 1 to 1½ ft. between the sets. The planting should be closer in poor soils and wider in rich soils. 14 lb. of tubers will plant a rod of ground.

The only cultivation necessary is hoeing to keep down the weeds and the drawing of a little earth to the stem. The surface of the soil should be stirred during dry weather.

The tubers do not suffer from frosts and may be left in the ground and lifted as required; or, to get over the difficulty of digging the tubers in frosty weather, they may be lifted in November and stored in sand in a cold shed or cellar, or they may be clamped in the open like potatoes. They should not be exposed freely to the air, or they become soft very quickly.

The fork should be used in lifting and care should be taken to remove all the tubers, otherwise they will grow in the following year.

For use as pig food, artichokes should be cooked when fed to small pigs, but sows will take them raw. Under field cultivation and after the crop has been lifted pigs turned into the field will clean the ground by picking up the small tubers left in digging, and a further advantage of thus turning in pigs will be the increased fertility of the ground.

New Allotments.—Up to 30th March, 1918, 251,474 new allotment plots had been arranged for under the Cultivation of Lands Order by local authorities acting in co-operation with the Food Production Department. The Department also report that, in consultation with twenty-six local authorities arrangements were made in the week ending 30th March for the laying-out of 6,183 additional allotments, covering an area of 401½ acres. Parts of the Royal Parks in London are also to be cut into allotments, some 5 acres of land in Kensington Gardens having been set apart for this purpose by the Office of Works.

Allotment Rivalry.—Especially in the North Country there is keen rivalry among local authorities as to which shall supply the largest number of allotments per 100 inhabitants. In

Yorkshire some of the councils are trying to get an allotment for every three inhabited houses if possible. Amongst other townships that have accomplished this are Keighley and Ossett ; indeed, more than half the householders in these places have allotments. The task of the bigger towns is more difficult, of course, but Leeds has one allotment for every thirteen houses and Bradford one for every ten. In Yorkshire alone about 1,600 acres of land are being taken over for allotments by local authorities.

Crops to Grow.—There are two distinct directions in which an allotment holder may aim. Firstly, to obtain a supply all the year round for home consumption, in which case probably one-half of his ground will be taken up by potatoes, and the remainder largely devoted to the most essential vegetables ; or, secondly, to produce entirely or partly for market, which would necessitate larger areas being devoted to say three or four varieties of vegetables so as to permit selling in quantity. The first object will be that commonly pursued ; and, working on these lines, it is advisable to prepare a rough plan of the ground, marking out the crops for two or three years, so as to secure a proper rotation and to calculate one's seed requirements.

Be sure to get the best seeds available, for this invariably proves to be the most economical system in the end.

The principal aim will be to grow as much as possible of those vegetables which have the highest food, or dietetic, value ; and the following are among such vegetables : potatoes, onions, leeks, parsnips, Jerusalem artichokes, broad and haricot beans, celery, and beetroot, for general use ; Brussels sprouts, kales and savoys for winter and spring supplies of green vegetables ; and pumpkins for winter storing.

There is also a secondary matter to bear in mind ; this is that owing to the prospect of very diminished supplies of food of fine flavour, such as cheese, butter, fish, meat, etc., seasoning vegetables such as shallots, lettuce, chives, radish, endive, ridge cucumbers, mustard and cress, chioory, garlic, etc., may well be grown, where possible, in addition to savoury herbs, such as parsley, mint, thyme, sage, etc.. These all assist in making tasty dishes and salads, thereby helping to economise the use of meat, fats, and other scarce foods.

Where it can be done, tomatoes should be grown also with this object in view.

The question of varieties to be grown is very important, and local experience only can teach which are best for the allotment holder. In some places a certain kind will do remarkably well, whereas in another district it may prove a very poor sort to grow. The would-be cultivator should select when possible those which are known to succeed in his locality.

At the time of sowing seeds, steps should be taken to combat the attacks of birds, pests, etc., by wire-covers, string-nets, or cotton strands and by sprinkling of soot and lime between the rows.

Fertiliser Prices.—In reply to inquiries, the Food Production Department states that the South Metropolitan Gas Company and various other concerns are now making up 7-lb. packages of sulphate of ammonia for sale at 1s. 6d. to allotment holders. Most of the retailers of fertilisers should be in a position to supply sulphate of ammonia approximately at this price. The March price for superphosphate is about 8s. 9d. per cwt. in London. Secretaries of gardening, allotment, small holdings, and similar societies can obtain lists of fertiliser firms from the Food Production Department, 72, Victoria Street, S.W. 1.

Structures on Allotments.—In some parts of the country certain persons are objecting to the erection of "unsightly structures" on allotment plots and have attempted to get local authorities to prohibit their erection. The Food Production Department has no sympathy with such sensitive people, and that where it is more convenient that workmen should have tool sheds on allotments, instead of carrying their tools backwards and forwards for long distances, the Department trusts that local authorities will do nothing to prevent the most efficient cultivation of allotment plots. The example of authorities in the North Riding of Yorkshire may well be followed where this difficulty arises, the local allotment association being asked to undertake the supervision of the erection of any tool sheds or other structures on the allotment ground.

THE work of the tractor on the land has naturally excited a great deal of popular interest and appreciation because of the novelty of the machine and its increasingly successful results. It is pointed out by the Food Production Department that a great deal of the credit for the advanced state of the agricultural programme is due to the older form of mechanism, known as the steam plough or steam tackle, and in our enthusiasm for the tractor we ought not to forget the debt due by the Nation to the steam-plough owners of the country.

In March, 1917, Sir Arthur Lee asked Mr. John Allen, the Chairman of the Steam Cultivation Development Association, to organise the steam-ploughing industry in England. At that time, owing to difficulties in procuring labour and material, a considerable number of ploughing tackles were not being worked. The Food Production Department immediately took steps to secure the return from the Army of a large number of skilled steam-ploughmen and also rendered assistance to the trade in other practical ways, bringing home to the steam-plough owners the national importance of the industry. The steam-plough owners promptly responded with an increased acreage of 40 per cent. The Department also took steps to procure a considerable number of new tackles, some of which are already at work. The tackles are not owned by the Food Production Department or the County Committees; they are all privately owned, principally by contractors, who plough by the acre.

It was considered that the best results could be obtained by allowing the steam ploughs to remain in the hands of their owners working under the direction and organisation of the Food Production Department, with the result that they have ploughed or cultivated during 1917 close upon 1,000,000 acres. The precise figure is just over 990,000 acres, to which can be added 80,000 acres since 1st January, 1918, making a total of 1,070,000 acres for the coming harvest. Thanks are due to the trade for keeping a considerable portion of their tackle at work throughout the winter, notwithstanding the fact that owing to short days and unsuitable weather the work was unremunerative.

OFFICIAL NOTICES AND CIRCULARS.

N.B.—The Orders mentioned below may usually be obtained at the price of 1d. each from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, and 28, Abingdon Street, London, S.W. 1; 37, Peter Street, Manchester; and 1, St. Andrew's Crescent, Cardiff.

THE following Circular Letter (No. 89/M. 6), dated the 11th March, 1918, was addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Organisation of Threshing.

SIR,—With reference to the Department's Circular Letter of the 27th February and previous correspondence respecting the organisation of threshing, I am directed to inform you that the Department have given further consideration to the arrangements which should be made for threshing the 1918 crop. They have come to the conclusion that there is no possibility of increasing substantially the threshing resources of the country by supplying large quantities of new tackle, and that the only means for arranging for the threshing of the increased corn crop which is expected to be harvested this year will be by improving the organisation of the existing resources. To carry this out efficiently the threshing industry must be organised on a county basis.

In a few counties steps have already been taken by Executive Committees to organise the industry in their area. The Department do not suggest that in such cases the scheme which has been adopted should be modified, provided that the Committee satisfy themselves that the arrangements made will be adequate to the needs of their area.

In other cases the Department urge Committees to give immediate consideration of the following scheme. It is not proposed to lay down hard-and-fast rules, but to outline proposals which your Committee should adopt to the needs of their area :—

Threshing Sub-Committee.—A Sub-Committee should be constituted to deal specially with threshing. The Sub-Committee should consist of two representatives of the threshing trade, with a member of the Executive Committee and a member of the Machinery Committee. With a view to the selection of representatives of the trade it may be necessary, in the first instance, for your Committee to call a meeting of the threshing contractors in the county. The local Forage Officer should also be invited to attend the meetings of the Threshing Sub-Committee in an advisory capacity. The Department understand that the War Office will be prepared to give him permission to do so.

The principal duty of the Threshing Sub-Committees will be to arrange that the tackle in the county is put into an efficient state of repair, provided with labour, and worked to the best national advantage. To ensure that existing tackle is fully utilised it will be necessary for the Sub-Committee to divide the county up into areas and allocate to each area sufficient sets to cope with the expected crop. This arrangement will only be brought into effect by the Sub-Committee co-operating with the trade, but from enquiries which the Department have made it is clear that the threshing industry are quite prepared to fall in with any well-considered scheme. In the event, however, of an individual owner unreasonably refusing to adhere to a scheme approved generally by the trade in the county, the Department will not hesitate to authorise the Executive Committee to commandeer his tackle so as to enable it to be operated by other contractors.

Labour.—The Sub-Committee will probably find that one of the principal reasons for threshing sets not being worked to their maximum capacity is the shortage of skilled men. To overcome this difficulty the Department will authorise the Sub-Committee to lend to contractors for the remainder of the present threshing season any surplus men who have been trained for tractor work. During the time they are under training with the threshing contractors the Tractor Representative will be instructed to pay their wages. At the end of the threshing season these men must return to the Tractor Representative until they are required for threshing the 1918 crop, when they will have to be paid by the threshing contractor. It is hoped that the Sub-Committee will be able to arrange by this means for an adequate supply of labour to be trained ready for next autumn.

Additional Supply of Threshing Machinery.—The Department will be prepared on the recommendation of the Sub-Committee to release, so far as the supply is available, threshing boxes now being manufactured to their order, to any of the owners who are working in association with your Sub-Committee. The supply, however, will not be great, and the Sub-Committee should endeavour to arrange for threshing boxes owned by farmers and landowners in the county to be loaned to contractors so as to be available for work throughout the district.

With regard to engines the Sub-Committee, in consultation with the local Forage Officer, will have to consider the date at which engines in the county under contract with the Forage Committee should be returned to their owners for threshing work; also to what extent tractors may be substituted for engines now employed by the Forage Committee for hauling.

The Department desire to press upon your Committee the urgent necessity of inaugurating a scheme on the above lines if any effective steps are to be taken to train additional men during the few weeks which remain of the present threshing season.

I am, etc.,

(Signed) H. L. FRENCH,

General Secretary.

THE following Notice has been issued by the Ministry of Munitions of War, 8, Northumberland Avenue, London, W.C. 2 :—

Farmers or contractors desiring to purchase **Traction Engines for new steam traction engines for agricultural Threshing and Other purposes must make application to the Agricultural Purposes.** Director, Agricultural Machinery Department, Ministry of Munitions of War, 8, Northumberland Avenue, London, W.C. 2. Such application must be accompanied by a recommendation from the local War Agricultural Committee; or the Board of Agriculture and Fisheries, in the case of England and Wales; the Board of Agriculture in the case of Scotland; or the Department of Agriculture and Technical Instruction in the case of Ireland; stating that it is in the urgent national interest that permission to purchase such traction engine should be given. It should be specially noted that the supply of new steam traction engines is at present limited, and as there are no restrictions on the purchase of second-hand engines the buying of these is recommended.

THE Field Services Section of the Food Production Department desire to request owners of threshing machinery in need of essential repairs to

**Threshing Machine
Repairs:**

Notice to Owners.

communicate in good time with the Department so that arrangements can be made for getting the machines put into proper order. From inquiries received, it seems probable that quite a number of threshing machines require partial overhauling or the supply of important parts. In many instances, no doubt, this work can be done locally with available material. Only where this is not the case, and the repairs are absolutely necessary to efficient working, should the Department be written to; but in such event the utmost promptitude is desirable so that there shall be no needless delay when the machinery is required. Applicants to the Department should be as explicit as possible in their statements as to the nature of the repairs to which attention is directed, and should state the names of the firms who will carry out the work.

THE following letter (No. 113/M. 1), dated the 28th March, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board:—

**Harvesting
Machinery for
1918 Harvest.**

SIR,—The Department desire to inform County Agricultural Executive Committees of the steps taken for the provision of harvesting machinery for the harvest of 1918. Orders have been placed for 5,000 binders and for a small number of reapers. No orders have, however, been placed for mowers (other than combined mowers and reapers) or horse-rakes, since it is considered that in view of the reduction of the area under hay there should be a surplus of these implements in the country, and Committees should arrange to hire or purchase locally any that are required; proposals for the purchase of such implements should, in accordance with the established rule, be submitted in the first instance to the Department.

2. *Binders*.—Although every effort is being made to secure delivery of 5,000 binders, it is not certain that the full number will be obtained in time for the harvest. The binders will be principally machines with a 6-ft. cut, but a small number of 5-ft. binders will be available. In the first place, any prisoner-of-war centres established in your county will be supplied with binders according to the number of teams of horses provided at those centres, approximately at the rate of one binder to every three teams. These binders will in each case have a 6-ft. cut. The number of binders already allocated for prisoner-of-war centres in your county is. . . . If this number is considered inadequate, application should be made for the *additional* number required.

In the second place, binders will be supplied for use with gangs supplied under F. P. 92. It is proposed that these binders also shall be chiefly 6 ft., and Committees are requested to state the number of binders required under this head. Six-ft. binders will also be supplied on application by Committees for use with tractors.

After binders have been allotted to prisoner-of-war centres and to Committees for use with horse-gangs and tractors, the balance, if any, will be available for distribution to Committees who may wish to hire them to farmers.

3. *Reapers*.—It is proposed to supply reapers in substitution for binders to counties where the former are particularly in request, but

the number available will, in any case be small, and Committees should not make application for reapers unless they are essential. The machines supplied will be chiefly combined mowers and reapers with back delivery and 4-ft. 6-in. cut.

4. *Binder Twine*.—It is proposed to supply binder twine to Committees in bulk; any twine supplied must be used exclusively for the Department's binders under their control. Great care must be taken that the twine is not used for any other purpose, and the bale should not be opened except in the presence of a responsible officer of the Committee. The requirements of prisoner-of-war centres will be met directly by the Department.

5. *Charges*.—The following charges are suggested :—

	s.	d.	
Binder, team of 3 horses, 2 men and twine . .	12	0	an acre.
Binder, tractor, 2 men and twine	12	0	„
(Where twine is not supplied 4s. an acre may be deducted.)			
Reaper, team of 3 horses and 2 men . .	8	0	„
Reaper, tractor and 2 men	8	0	„
Binder alone, without twine	2	6	„
Tractor with driver : minimum charge . .	6	0	„

The Department are prepared to consider variations from these charges to meet local conditions, but it is necessary in each case that cost shall be covered.

6. *Labour*.—Provision has been made in the scale of charges for two men to be employed with a team of three horses when used with a binder, and it is proposed that the second man shall keep the knives sharp and give other necessary assistance in order that no time may be lost. Where tractors are used, two men are in any case required. It will be observed that the Department anticipate that tractors will be employed in some cases to draw binders which are the property of farmers: the man on the binder may be supplied either by the tractor representative or the farmer, but in any case the farmer will be required to meet the charge for his wages.

7. *Applications for Binders, etc.*—Committees should submit as soon as possible an estimate of their requirements; the estimate should be carefully framed, after taking into consideration the number of binders allocated to prisoner-of-war centres. It will be convenient if the estimate is submitted in the following form :—

Number required.	Binders.		Reapers.	
	6 ft.	5 ft.	Back Delivery.	Side Delivery.
For Prisoner-of-war Centres* . .				
„ Horse Gangs				
„ Tractors				
„ Hire to Farmers				

Binder twine required cwt.

* The number of binders (if any) inserted under this head should be additional to those already allocated.

Committees will be asked to give consigning instructions when it has been decided how many machines can be allocated to each county.

The Department will be glad if this letter may be considered at an early meeting of your Committee, and if a reply may be received in this office not later than the 13th April.

I am, etc.,

(Signed) HUGH M. STOBART,

Director, Machinery Supplies.

The following Circular (No. 119/M. 1), dated 5th April, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board:—

Use of Tractors.

SIR,—I desire to direct the attention of Agricultural Executive Committees to the importance of making the fullest possible use of tractors in cultivating, cleaning and seeding land during the next two months.

The heavier types of tractor designed chiefly for ploughing are not always well adapted for cultivating land that has been ploughed up for spring crops; but light tractors (notably Fordson's and Burford Cleveland's) can be used on any land on which a horse may safely work.

Fordsons are now being distributed to Committees in considerable numbers, and unless urgently required to complete ploughing contracts, they should be set to work with cultivators, disc or drag harrows, rollers and drills immediately. Recent trials have shown them to be very well adapted for work with these implements.

If tractor implements are not always available, ordinary horse implements should be used. These can readily be hitched to the tractor, and Committees who have not got supplies at hand should requisition them from the Department without delay.

The very fine weather of the past two months has enabled all farmers to get well forward with the sowing of corn crops, and there is now an opportunity of cleaning land properly before roots are sown. The urgency and importance of this work cannot well be exaggerated. If the opportunities now given by the season are taken advantage of, the green crop fallows of 1918 will be clean, and the foundations for successful corn harvests in 1919 and 1920 will be laid.

For a second reason Agricultural Executive Committees should make the fullest use of light tractors in cultivating arable land during the next two months. Agriculturists in all parts of the country must be given an opportunity of gaining experience with tractor-drawn implements. As the result of their efforts to increase the area of arable land during the past year, farmers will have some 2,000,000 extra acres of stubbles to till next season. For the tillage of much of this large additional area, reliance must be placed on the tractor, and it is, therefore, most desirable that tractor-drawn implements should now be tested in different localities and the best types selected, manufactured, and distributed in suitable numbers to the districts in which they will be needed in 1919.

At present the Department are almost without information from Agricultural Executive Committees respecting the probable demand for implements within their areas, and, in its absence, estimates for future supplies can only be based on evidence of past sales. In the case of new implements, like disc cultivators, this indication is, obviously, of little value and must be supplemented by reports from each district.

Orders for implements of new types for delivery in spring, 1919, must soon be placed, and if the next two months are allowed to pass, and the experience of new implements which might be gained in them is not communicated to the Department before Midsummer, farmers cannot expect to secure such improved patterns as they may think desirable before 1920.

Additional copies of this letter are enclosed for the information of your District Committees, and a further supply will be forwarded to you if required.

I am, etc.,

(Signed) A. LEE,

Director-General.

THE following Circular Letter (No. 46/6L.2), dated 21st March, 1918, has been addressed to County Agricultural Executive Committees, County Borough Councils in England and Wales, and to the London County Council by the Food Production Department of the Board :—

**Sale of Horses
Order, 1917.**

SIR,—Experience has shown that there is a shortage of horses suitable for agricultural and the essential trades, and it has become more than ever necessary to protect these interests.

In some counties the shortage of horses for land cultivation is so pronounced that the Committees are experiencing great difficulty in obtaining the horses required for the increased cultivation programme. It is therefore *most important that before issuing any licence for the sale of a horse, full investigation should be made by the Committee through their parish representative to ensure that the horse is really surplus to the requirements of the holding concerned, having strict regard to any increased area of land which should be brought into cultivation on the holding, and that all surplus horses should be brought to the notice of the Board's Purchasing Officer.*

The condition of road transport having become seriously affected owing to a variety of causes, more reliance will have to be placed upon horse transport for essential trades. The Board of Trade have therefore appointed a Controller of Horse Transport who is vested with powers as to the disposal and distribution of the horse power of the country, other than horses engaged, wholly or mainly, in agriculture or Army horses.

It will, however, be necessary for the Controller to make some demands upon the surplus agricultural horses, and the Department have agreed to assist the Board of Trade by placing at the disposal of purchasers authorised by the Controller of Horse Transport such *surplus agricultural horses as may not be required by the Army or the Board's Purchasing Officers.*

I am accordingly to request that licences issued in respect of horses so released from agriculture shall have the words "*or the Controller of Horse Transport*" inserted in Clause No. 1 of the form of licence after the words "Army Council," as a person who may authorise the purchase of the horse.

In view of the shortage of horses, and because considerable leakage has been taking place, it has been found necessary to alter the form of licence so as to limit the sale to—

- (a) An occupier of an agricultural holding *who purchases it for use wholly or mainly for the cultivation of that holding, and who*

shall, before delivery of the horse, sign the attached statement* to that effect; or

- (b) A person duly authorised by the Board of Agriculture and Fisheries or the Army Council to purchase the horse.

Note.—To sub-section (b) Committees will add the words "or the Controller of Horse Transport" after the words "Army Council," in certain cases as indicated above.

The alteration in the form of licence will have the effect of shutting out occupier dealers as dealers, but owing to the fact that the Army Council, the Food Production Department, and the trades represented by the Controller of Horse Transport (such as railway companies, etc.) must have the service of collector dealers, it is proposed to licence dealers separately under conditions which are at present under consideration.

Each of the Departments concerned will licence its own dealers, and Agricultural Executive Committees are asked to forward to this Department the names and addresses of a limited number of reliable dealers resident in their area.

The new form of licence for the Sale of Horses Order is now in the printer's hands and a supply will be sent to each Committee shortly.

In future the Department would be glad to be informed, at the end of each month, of the number of licences issued by your Committee, and as to how many of these were in favour of the Controller of Horse Transport.

I am, etc.,

(Signed) ARTHUR LEE,
Director-General.

THE following Circular Letter (No. 14/H), dated 19th March, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board:—

**The Formation of
Horticultural
Sub-Committees.**

SIR,—I desire to call the attention of your Committee to the urgent necessity for the formation of a Horticultural Sub-Committee for the purpose of stimulating the production, marketing, and conservation of food by allotment holders and small cultivators generally in your county.

The functions of such a Horticultural Sub-Committee are dealt with in the enclosed memorandum, and a study of the subjects referred to in the memorandum will, I feel sure, convince your Committee both of the importance and urgency of at once establishing a Horticultural Sub-Committee of the County Agricultural Executive Committee, if this has not already been done.

To mention two of the subjects referred to in the Memorandum, viz., the need of taking immediate steps to secure the marketing of surplus produce grown by small cultivators, and the importance of increasing the amount of livestock suitable for keeping by small cultivators, will suffice to show that the Food Production Organisation of the county cannot be considered complete until the horticultural aspect of these subjects has been dealt with upon the lines suggested in the Memorandum.

* Not here printed.

It is the desire of the Food Production Department that horticultural work in the county should be regarded as an integral part of food production. It is recognised at the same time that the Agricultural Executive Committees are so fully occupied with the important services which they are rendering to agriculture as to be unable to assume as part of their routine duties the promotion of horticultural food production, and it is for these reasons that I have to ask the County Executive Committees to take, without delay, the necessary steps for establishing the Horticultural Sub-Committees referred to in the Memorandum.

I shall be glad to be informed in each case when this has been done.

Yours faithfully,

A. LEE,

Director-General.

ENCLOSURE.

At a recent conference, presided over by the Director-General of the Food Production Department, which was attended by representatives of county and other organisations, on the subject of marketing surplus food produce, it was unanimously resolved to further the Department's proposal for establishing Marketing Committees in each county of England and Wales.

It is considered by the Food Production Department that the organisation of marketing as well as that of food production by small cultivators should be entrusted to the Sub-Committee of the Agricultural Executive Committee.

In many counties a Horticultural Sub-Committee has already been appointed by the Agricultural Executive Committee and has, with the assistance of District and Village Committees, formed an effective County Organisation. It is important that this course should be adopted immediately in all counties.

The main objects with which the Horticultural Sub-Committees would concern themselves are :—

- (1) To encourage and co-ordinate schemes for cultivating ground by small cultivators and allotment holders.
- (2) To inquire into the existing County Organisations for promoting food production by small cultivators and allotment holders, and, where necessary, to secure that in each rural and urban district and in each borough there is a district or borough Horticultural Food Production Committee.
- (3) To nominate, where necessary, new horticultural representatives for appointment by the Department and to revise the existing list of horticultural representatives with a view to dispensing with the services of those whose work is not considered to be satisfactory.
- (4) To secure the formation of an Executive Marketing Committee for the purpose of marketing the surplus produce grown in allotments and gardens.
- (5) To advise the Food Production Department on the most economical and effective means of employing in the county the Department's staff of special lecturers and demonstrators for the purpose of supplementing the local supply of lecturers.

- (6) To promote schemes for the keeping of live stock, such as rabbits, poultry, etc., and bees by small cultivators and allotment holders.

In those counties where a County Horticultural Committee has already been formed the Department would suggest that the existing Committee should be recognised by the Agricultural Executive Committee as its approved agent or authority for the purpose of horticultural work in the county, but in such cases it is nevertheless considered necessary that the Agricultural Executive Committee should secure that any Horticultural Committee now in existence should be reformed as a Sub-Committee of the Agricultural Executive Committee.

The Horticultural Sub-Committee should, wherever possible, consist of :—

- (1) A chairman selected for his special interest in horticultural subjects, who is either a member of the Agricultural Executive Committee or of the War Agricultural Committee.
- (2) A representative of the Women's War Agricultural Committee.
- (3) A representative of the Local Education Authority.
- (4) Two of the existing Rural District, Urban District or Borough Horticultural representatives.
- (5) Ex-officio members : the Department's District Commissioners and Sub-Commissioners.

The Department are not anxious that the Horticultural Sub-Committee should be large, but at the same time they consider that it should be thoroughly representative of the horticultural interests of the county. The Department deem it desirable that, where the assent of the County Council can be obtained, the Horticultural Instructor or Advisor to the County Council should act in a similar capacity to the Horticultural Sub-Committee and, in particular, should undertake the general direction in technical matters of the horticultural representatives in the county.

The County Horticultural Sub-Committee would proceed to form Horticultural Food Production Committees in each urban and rural district, and these in turn would form Village Committees. In many cases these Committees are already in existence and are actively carrying on the work of Food Production, and it only remains for them to be linked up with the County Horticultural Sub-Committee.

In the case of boroughs which are at present outside the scope of the County Horticultural Sub-Committee, an amicable arrangement might be come to whereby the whole area would come under the Horticultural Sub-Committee.

Horticultural representatives for separate districts and boroughs would continue to be appointed by the Department, but only on the nomination of the Horticultural Sub-Committee. They should act as technical advisors to the District and Borough Horticultural Food Production Committees in the same way as the County Horticultural Instructor or Advisor acts in relation to the County Horticultural Sub-Committee. The horticultural representative should be instructed to report to the Sub-Committee and not to the Department.

The Department allow a grant of £10 a year for the out-of-pocket expenses incurred by each horticultural representative, and it is proposed to ask the Horticultural Sub-Committees to pay this sum out of a block grant to be provided by the Department.

The Department have approached the Treasury for sanction to pay a salary to the Secretary of the County Horticultural Sub-Committee on the following conditions :—

- (1) The Secretary should be nominated by the Sub-Committee, but his appointment should be approved by the Department.
- (2) Having regard to the fact that the most immediately pressing duties of the Sub-Committee would be to make provision for the organisation of the marketing of the surplus produce raised by the small cultivator and allotment holder, the Sub-Committee should at once proceed to appoint a County Marketing Executive Committee on the lines of the Memorandum on Marketing provided by the Department.
- (3) Wherever possible the Secretary of the Sub-Committee should also act as Secretary of the Marketing Executive Committee. In cases where this is not found possible the Horticultural Sub-Committee will be asked to submit proposals to the Department for the allocation of the salary as between the two secretaries whom it may be necessary to appoint.

THE Prime Minister issued in March the following appeal to farmers and others to grow more potatoes :—

The Prime Minister's Appeal for a Million Acres Under Potatoes. " I desire to impress upon all farmers and small growers the vital importance of increasing to the utmost extent possible the supply of potatoes this year.

There is no crop under existing war conditions which can compare with it in importance as a food for either man or beast, and it would be quite impossible to plant too many potatoes this spring.

Last year I appealed to the farmer to grow more potatoes, and he responded by beating all records. This year I appeal again, and with even greater earnestness, because the need is twice as great.

If we can get a million acres under potatoes in Great Britain this year, the food situation will be safe, and farmers will have rendered an immense service to their country.

The potato-grower is in the front line of the fight against the submarine. He can defeat it if he chooses, but victory depends on his action and exertions during the next few weeks."

(Signed) D. LLOYD GEORGE.

THE following Press Notice was issued by the Food Production Department on 5th April :—

Potato Growing : Urgent Need for Greater Activity. British farmers as a body have responded admirably to the call of the Government for increased production ; and the outlook for our corn crop is extremely encouraging. Unfortunately, the potato prospect is by no means so satisfactory. Up to the present it is doubtful whether as much land has been prepared for potatoes this season as last ; and it is hardly to be expected that the 1918 yield will be as large as that of the 1917 crop, which was well above the average.

The Prime Minister a few weeks ago appealed to farmers to grow more potatoes this year than last year, when, in response to his earlier

appeal, the farmer beat all records of potato planting in England and Wales. A certain number of large growers have been moved by the Premier's recent message to arrange for the growing of more potatoes, but this movement does not seem to be general.

As the Food Production Department points out, the situation is most serious. We need 1,000,000 acres of potatoes in Great Britain this year to make the food situation safe, and only the farmers can give us this 1,000,000 acres. We want another 1,500,000 tons of potatoes grown this year—apart from the allotment holder and gardeners' crops; and only the farmers can grow them. As things now look, there is reason to fear that we may be as much as 400,000 acres short of our probable requirements in potatoes during 1918. This must be prevented at any cost.

Many farmers have protested against the proposal that they should increase their 1918 acreage under potatoes because they have been unable to sell satisfactorily a large part of their 1917 crop. The Ministry of Food has met them in this difficulty on quite liberal lines. *On 15th May, 1918, the Food Controller will purchase all sound ware potatoes in the United Kingdom for which the grower cannot otherwise find a market. The Food Controller will pay not less than £7 per ton for 4-ton lots f.o.r.* Whilst the base price for potatoes will remain unaltered until further notice, compensation claims will be based on the minimum price of £7 per ton on and after 15th May, as compared with the minimum price of £6 10s. from 15th April. Every farmer who redresses his clamps for the purpose of extracting the seed for planting or for sale for planting and reclaims the ware will receive from the Ministry of Food an additional 10s. per ton for each ton of sound ware potatoes subsequently sold from the new clamps.

These concessions in relation to the remainder of the 1917 crop should induce many hesitating farmers to increase their 1918 acreage of potatoes. The Ministry of Food has already guaranteed to buy at minimum prices of from £6 to £7 per ton all the crop grown on new land this year and to pay a generous price for the remainder of the 1918 potato crop—prices for the latter being fixed by a Joint Commission of the Board of Agriculture and the Ministry of Food after visiting each area and taking evidence from the growers as to yields, cost of production, etc.

It will be seen that potato growing by farmers this year promises to be a very sound business proposition. It is also a patriotic duty of the highest importance. That the farmers of the country will not rise to the level of the occasion is unthinkable, after their remarkable achievement in the matter of corn crops.

A VIGOROUS campaign has been inaugurated by the Ministry of Food with the object of securing an increase in the acreage under potatoes in those counties of England and Wales which, if they are to become self-supporting in the matter of potato supplies, have to wipe out a deficit on last year's crop by planting seed within the next few weeks more extensively than ever.

**More Potatoes
Wanted: Scheme of
Ministry of Food
to Make Counties
Self-Supporting.**

Details of the Ministry's scheme for dealing with the 1918 crop have already been published in this *Journal*.* For

* February, 1918, pp. 1222-3.

the information of agriculturists, market gardeners and allotment holders, those arrangements may be briefly reiterated as follows :—

* Every grower of potatoes will have a free market for the sale of his produce up to 1st November.

On 1st November the Food Controller will take over the crop at a purchase price which will be assessed by a Joint Commission appointed by the Food Controller and the President of the Board of Agriculture. This Commission will visit various districts of the country and examine the general average size of the crop in the district, the quality of the potatoes, and the general average cost of production. They will then assess the final purchase price of the crop for the district ; but in any case this final purchase price will not be less than an average (according to time of delivery) of £5 15s. per ton for those sound ware potatoes which naturally fetch the lowest price in the market. This bottom figure in the scale of purchase price has been fixed in relation to the average cost of production in the fen lands of Cambridgeshire, where potatoes are usually produced most cheaply. It is important to notice that as the minimum purchase price will be calculated on this basis, the actual purchase price in other districts will be proportionately advanced if it can be proved to the Commission that this minimum price will not secure an adequate return for the farmer.

The advantages of this policy over the 1917 arrangement will be obvious. In 1917 a flat price of £6 per ton for all farmers and all classes of potatoes was guaranteed. The inevitable result was that every purchaser of potatoes naturally wanted the best quality, and it was difficult to secure a market for the cheaper qualities. Under the 1918 arrangement people who want a better quality of potato will obviously have to pay a higher price for it, and those who produce the cheaper qualities will not be robbed of their natural markets, and, moreover, growers will have an absolutely sure market for potatoes.

With a view to economy in transport, the distribution of potatoes will probably be effected by dividing the country into different zones, a zone being approximately of the size of an average county. The general idea is that people living within any zone should be encouraged if possible to grow all the potatoes they require ; but if it is proved impossible the deficit required for consuming purposes will be drawn, not from distant parts of the country, but from the nearest surplus zone.

COUNTIES WHICH SHOW A DEFICIT.

The following table shows, in round figures, the counties where deficits exist, and the Ministry invites the co-operation of all growers in those counties to make this scheme of supplies a success :—

<i>County.</i>	<i>Produced.</i>	<i>Consumed.</i>	<i>Deficit.</i>
	<i>Tons.</i>	<i>Tons.</i>	<i>Tons.</i>
Rutland	1,400 ..	1,800 ..	400
Oxford	16,200 ..	16,700 ..	500
Isle of Wight	3,900 ..	7,700 ..	3,800
Wiltshire	19,200 ..	26,900 ..	7,700
Buckingham	13,300 ..	21,100 ..	7,800
Dorset	12,300 ..	20,200 ..	7,900
Northampton	16,000 ..	27,300 ..	11,300
Berkshire	11,100 ..	26,100 ..	15,000
Nottingham	42,300 ..	58,200 ..	15,900
Somerset	24,800 ..	41,800 ..	17,000

County.	Produced.		Consumed.		Deficit.
	Tons.		Tons.		Tons.
Suffolk	24,500	..	42,400	..	17,900
Leicester	15,900	..	46,000	..	30,100
Monmouth	8,700	..	39,600	..	30,900
Sussex	26,600	..	58,900	..	32,300

Middlesex	17,100	..	117,000	..	99,900
Lancaster	351,800	..	455,500	..	103,700
London	2,300	..	423,800	..	421,500

It is well-known that there are certain potato-producing areas in the country whose task in years gone by has been to supply the necessary potatoes for the non-producing areas. If there is any fear that the present scheme may rob the producing areas of their markets, that fear may be dispelled by pointing out the arrangements that are in course of completion for the erection of factories in these producing areas to absorb any available surplus for the manufacture of potato flour and other products, which incidentally will yield valuable by-products for cattle food.

It is not proposed to compel any allotment holder to sell his produce ; but if any number of allotment holders like to group themselves into an association, affiliated to the County Associations of the Food Production Department, and, after having provided for their own requirements, they have a surplus of which they wish to dispose, the Ministry of Food will purchase that surplus on exactly the same terms at which they are purchasing from farmers. Apart from the ordinary purchase price of the crop, the Ministry is prepared to enter into forward contracts for the produce of any acreage in excess of what was planted in 1916. The contract price for potatoes of this description has been fixed (according to the time of delivery) at an average of £6 10s. per ton ; but there is a Clause in each contract that in no case will this contract price be allowed to fall below the final purchase price assessed by the Joint Commission. (*The National Food Journal*, 27th March, 1918.)

THE following Notice was issued to the Press by the Food Production Department of the Board on 8th April :—

There is still time to reach the increased
The Potato Crop: The acreage of potatoes appealed for by the Prime Question of Fertilisers. Minister a fortnight ago ; and, in the interests of national security, no obstacles such, for example, as local scarcity of farmyard manure or sulphate of ammonia, should be allowed to stand in the way. Grass land is generally in a condition to produce satisfactory crops without the aid of such manures,

particularly if, on ploughing, it breaks into a loose friable tilth, and so long as a dressing of about 4 cwt. per acre of superphosphate is available, other manures may be largely, if not entirely, dispensed with.

THE following Letter (No. 22/S.2), dated 28th March, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**The Supply of
Seed Potatoes.**

SIR,—In view of the urgent necessity for increasing the acreage under potatoes in England and Wales in 1918 I invite your Committee to co-operate with the Department in providing facilities for the distribution of further quantities of seed potatoes of approved main crop varieties to allotment holders, cottagers, small holders and farmers in your county during the next few weeks, while planting is still possible.

The Department are prepared to give prompt delivery through Agricultural Executive Committees, approved seed potato dealers, allotment societies and food production societies in your county on the lines of the existing scheme, and your Committee can also supply farmers with any quantity of not less than 4 tons of one variety.

I greatly appreciate the efforts which have already been made by your Committee to increase food production, but I feel that the potato crop is of such vital importance to the nation during the coming year that a very special effort should be made to secure the area of 1,000,000 acres for which the Prime Minister has so earnestly appealed.

I have arranged for a supplementary supply of "seed" to be put at the disposal of the Executive Committees in order that every possible aid may be given to those growers who can be induced to increase their acreage, and the Department will send you particulars of varieties and quantities with their prices on application.

The Ministry of Food is about to issue an announcement as to this year's crop, of which an advance copy will be sent to you. It will, I feel sure, show the anxiety of the Government to give full consideration to the interests of potato growers.—I am, etc.,

(Signed) A. LEE,

Director-General.

THE following Notice was issued to the Press by the Food Production Department of the Board on 8th April :—

**Onions :
The 1918 Crop.**

The attention of all growers of onions is drawn by the Food Production Department to the following announcement with respect to the 1918 crop :—

"In view of high freights and restrictions in shipping it is extremely important that the home production of onions should be increased very largely and up to the fullest extent which the supply of seed will allow. In the notice issued by the Department on the 7th March, it was stated that the Ministry of Food had fixed prices for onions. The statement should have read as follows : The Ministry of Food announces that in the event of it becoming necessary to fix any maximum growers' prices for the British Onion Crop of 1918, the prices will not be less than those indicated in the following scale :—

Early Autumn (up to 1st November) ..	£15	f.o.r., f.o.b.
Late Autumn (1st Nov. to 1st Jan.) ..	£16 10s.	"
Winter and Spring (after 1st January) ..	£18	"

THE following Memorandum (No. 40/C. 1), dated 30th March, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**The Sowing of
Seed Mixtures.**

Inquiries have been addressed to the Department as to the policy which should be adopted in sowing seed mixtures during the present spring. In view of the shortage of feeding-stuffs, the hay crop is likely to be specially valuable in 1919, and it is desirable that farmers should sow the normal area of "seeds" for one year's ley. On the other hand, a reduction is desirable in the sowing of two and three year leys, and only in exceptional circumstances should the sowing of mixtures of permanent grasses be permitted.

THE following Notice was issued in March by the Food Production Department of the Board :—

**Bare Fallows
or Crops.**

The Food Production Department strongly recommends farmers to reduce to the lowest possible limit the area under bare fallow. Advantage should be taken of the fine weather to clean foul land; and, should the season continue favourable, a large proportion of the land usually fallowed might be put under crop. Tractors are available for cultivating, cross-ploughing, etc., for which purposes they compare favourably with any other means of cultivation. Farmers desiring to hire tractors should apply to their County Agricultural Executive Committee.

THE following Notice, dated 22nd March, 1918, has been issued by the Food Production Department of the Board :—

**Superphosphate
Supplies: Important
Notice.**

Owing to an unexpected increase in the output of superphosphates, there is a possibility that farmers and allotment holders may be able to secure additional supplies. They should place their orders at once with their usual merchants or co-operative societies, even if they require delivery as late as May.

If merchants say that no further supplies are available, inquiry should be addressed promptly to the Food Production Department, 72, Victoria Street, S.W. 1.

Superphosphates are especially valuable in increasing potato crops. An Order is about to be issued fixing the prices for the sales of small quantities from merchants' stores.

THE following Notice was issued towards the end of March by the Food Production Department of the Board :—

**Sunflower Seed
Prices.**

It has been brought to the notice of the Food Production Department that growers are unable to obtain supplies of American Giant Sunflower Seed at the prices mentioned in the Notice recently issued by this Department,* viz., 3d. per oz., 9d. per 4 oz., or 1s. 3d. per 8 oz. A considerable quantity of this variety of sunflower seed has recently been released at a price which enables retail seedsmen to sell at these rates. The Department will be glad

* See page 1467 of this *Journal* for March, 1918.

to supply retail seedsmen with the names of the wholesale firms from whom they can obtain supplies of this seed.

The seeds of the Giant strains of sunflower are rich in oil and a valuable food for poultry, and it is very desirable that they should be cultivated on vacant land which is not suitable for food crops.

Full information as to cultivation and harvesting can be obtained from the Food Production Department, 72, Victoria Street, S.W. 1.

THE following Notice was issued towards the end of March by the Food Production Department of the Board :—

A serious disease of celery, called Celery
Celery Leaf Blight. Leaf Blight, is often the cause of the partial or complete failure of the crop. The disease may be recognised by local crumbling of the leaf followed by the appearance of spots on the surface of the leaf, and when the attack is serious the stalk rots.

Since the disease is often carried in the "seed," growers of celery are advised to disinfect their seed. In order to do this, hydrogen peroxide should be used.

When purchasing hydrogen peroxide, if it can be had, a solution known as 20-volume solution should be bought, but if that cannot be obtained a 10-volume solution may be used. The seed to be treated is placed in a glass or earthen vessel and enough of the hydrogen peroxide poured into it to cover the seed completely. Stir the mass thoroughly so that all the seeds become wet. Allow the seeds to remain in the liquid for 3 hours and then pour the liquid off and use it a second time if required. Spread the seed in a thin layer in the air before sowing. Do not return the seed so treated to the original packets or else some of the spores of the fungus causing the disease adhering to the paper of the packets may re infect the seeds. If carried out carefully no damage to the seeds results, and the celery will have the chance of remaining free from the disease.

It may, however, become infected later on, and in that case the disease may be checked by spraying with Bordeaux or Burgundy mixture. The spraying should be begun at the first sign of the disease and must be repeated if the first spraying does not check it.

For instructions for making Bordeaux mixture, see Leaflet F.P. 142/H., "Potato Disease and its Prevention," which may be obtained on application to the Director-General, Food Production Department, 72, Victoria Street, S.W. 1.

THE following Notice was issued towards the end of March by the Food Production Department of the Board :—

Household soot is a valuable manure and
The Value of Soot. insect deterrent.

Where possible, the Food Production Department advises allotment holders to arrange, when having their chimneys swept, to keep the soot for use as a manure.

Good soot contains at least 3 per cent. of nitrogen, and is specially suitable for all members of the cabbage family and the onion crop, as well as being beneficial to all crops during the early summer, if sown between the rows. It also darkens the colour of the soil, and increases its power of absorbing heat.

A dressing equivalent to the usual application of sulphate of ammonia would be at the rate of 10 cwt. or 40 bush. per acre, or 7 lb. per rod. Heavy applications should not be given to the foliage of tender crops such as carrots, or burning may result.

Soot should be stored under cover for a time before it is used on a growing crop. A good sample weighs 28 lb. per bush.; heavier samples are usually of poorer quality.

AN Order (No. 325), dated 16th March, 1918, has been made by the Food Controller providing that :—

The Live Stock unless such beast has within the 14 days
(Restriction of immediately preceding the day of slaughter
Slaughter) Order. been sold or bought in a market in Great Britain.

2. (a) No person shall bring or send or cause to be brought or sent to any market for sale for slaughter or sell for slaughter, or cause or permit to be slaughtered, any in-pig sow of any age, in-lamb ewe of any age, in-calf cow, or in-calf heifer, or any calf.

(b) An animal shall be deemed to be brought or sent or sold for slaughter if it is slaughtered within 14 days of its sale in the market to which it was brought or sent or in which it was sold.

3. The prohibition contained in Clause 2 hereof shall not apply to—

(a) Calves of the Ayrshire breed born in Scotland ; or

(b) The slaughter of a calf which has been marked by a person authorised by the Food Controller in that behalf in the manner prescribed by this Clause and which bears such mark at the time of slaughter.

4. (a) The prescribed mark shall for the purpose of Clause 3 of this Order be a broad arrow branded in hot pitch or a mixture of hot pitch and tar on the head, the shaft and two barbs of the arrow to be a $\frac{1}{4}$ in. in width, and the length of the shaft and of the barbs (outside measurement) to be $2\frac{1}{2}$ in., or such other mark as may from time to time be prescribed by the Food Controller.

(b) No person shall mark any calf with the prescribed mark or with a mark colourably resembling the prescribed mark unless he be authorised in that behalf by the Food Controller.

5. The restriction of slaughter imposed by this Order shall not apply to :—

(a) Slaughter of an animal under the powers conferred by the Diseases of Animals Acts, 1894 to 1914, or any Order made thereunder.

(b) Slaughter of an animal when such slaughter is authorised by an officer of the Board of Agriculture and Fisheries or the Board of Agriculture for Scotland.

(c) Slaughter of an animal when such slaughter is immediately necessary or desirable on account of accidental injury to the animal or of its illness, or for any other exceptional reason or purpose. Provided that notice of such slaughter shall be given within 7 days thereafter to the Food Control Committee for the district in which the owner of the animal is at the time of the slaughter residing.

6. For the purpose of executing and enforcing this Order any officer of, or other person authorised by, the Food Controller may enter into any slaughter-house or other premises on which he suspects animals are being or have been slaughtered for human food and examine any animals or carcasses or hides therein, and inspect and require production of any books, or other documents relating to animals slaughtered on such premises; and no person shall impede or obstruct such officer or other person in the exercise of his powers under this Clause.

7. No meat obtained from any calf born in the British Islands shall be sold, supplied, or offered or exposed for sale for human consumption except :—

(a) To persons who in the ordinary course of their business are manufacturers of sausages, meat pies and other similar articles for the purpose of such business; or

(b) As an ingredient in a sausage, meat pie or other similar article.

9. The Live Stock (Restriction of Slaughter) Order, 1917, is hereby revoked as on the 18th March, 1918, but without prejudice to any proceedings in respect of any contravention thereof.

THE Food Controller by an Order (No. 374), dated 28th March, 1918, has made the following Amendment to the principal Order (No. 903 of 1917*) as subsequently amended by Order No. 247 of 1918* :

**The Meat
(Maximum Prices)
Amendment Order,
1918.**

1. The Schedule to this Order shall, as from the date hereof, be substituted for the present Schedule to the principal Order which shall as from that date be construed as if it had originally been made with such substitution.

2. The General Licences issued under the Principal Order, dated 24th December, 1917, and 14th January, 1918, are hereby revoked.

Schedule of, Maximum Wholesale Meat Prices.

Beef and Veal, price per stone.			Mutton and Lamb, price per stone.	Pork, price per stone.
Home Killed.	Imported.		Home Killed and Imported.	Home Killed and Imported.
Carcass. s. d. 8 2	Hindqtrs. s. d. 9 3	Foreqtrs. s. d. 7 1	Carcass. s. d. 8 8	Carcass. s. d. 10 8

NOTE.—In ascertaining weights, the offals are to be excluded. In the case of pork, other than imported pork, the maximum rate of 10s. 8d. per stone is applicable if the offals are not included in the sale, and the maximum rate shall be 6d. higher if the offals are included in the sale. In each case the weight of the offals shall be excluded in ascertaining the weight of the carcass.

* See this *Journal* for September, 1917, p. 678, and for March, 1918, p. 1473.

THE recent announcement with regard to the duration of the present maximum price for fat cattle will allay any uncertainty that may have been felt by farmers in laying their plans for

The Maximum Price for Fat Cattle.

next year. The maximum price of 75s. per cwt. for cattle of the first grade or its equivalent in dead weight will not be lowered before June, 1919. Lord Rhondda has had under consideration the question of fixing the price of store cattle, on the ground that it is desirable in fixing a maximum price at one end of the scale to ensure that prices are controlled in the first stages of production. It is evident that where store cattle have been purchased in the ordinary competitive market the grazier, who is compelled to sell fat cattle at controlled prices, may make less profit than that to which he may claim to be entitled. The practical difficulties urged against fixing the price of store cattle have, however, so far proved insuperable. The matter was referred to the Sub-Committee of the Central Advisory Committee on Live Stock and Meat Supplies, and they have reported against any attempt to secure direct control or grading of store cattle beyond limiting sales to the extent that they should only pass through the hands of one dealer on the way from the breeder to the grazier. An exception must, of course, be made with regard to Irish stores, since a British as well as an Irish dealer is required. Acting on this advice, in which the Boards of Agriculture concur, Lord Rhondda has decided not to fix the price of store cattle.

Although control of store prices has been found impracticable at the moment, farmers will be able, now that the duration of the present price of cattle has been guaranteed to the middle of next year, to estimate what price they can afford to pay for stores, and it is hoped that in these circumstances the inflation which took place last year will not be repeated. In any case, the payment of inflated prices for stores cannot be accepted as a valid reason for any new increase in the maximum price of fat cattle. The position of the producer has been further improved by the increase in the maximum price which is to be paid to the farmer for cattle sold on the basis of the yield in meat. This dead-weight price has been increased from 9s. 2d. to 9s. 6d. a stone of 8 lb., or 1s. 2½d. a lb., to be paid on the weight of the dressed carcass and to include offal.

The objections raised by farmers to sales on the dead-weight basis have been mainly that the uncertainties with regard to weighing and identification were insuperable, and that the cattle would lose weight during a possible longer transit and delay before slaughtering. After consultation at the Ministry of Food, however, many of the misgivings of farmers with regard to sales on the new basis have been removed, and a provisional agreement has been reached. Wherever practicable authorised slaughter-houses run on co-operative lines by the farmers themselves will be established so that they can themselves supervise identification and weighing. The slaughter-houses will, as far as possible, be in the agricultural districts, so that difficulties will be reduced to a minimum. The change to the dead-weight basis will be effected gradually, and in every case only when satisfactory arrangements for slaughter and identification have been provided. Moreover the option as to whether sales should be on the live-weight or the dead-weight basis is left in the hands of farmers. Under the conditions necessitated by the coming of compulsory rationing throughout the country it is essential that exact estimates of the meat coming into any

area and, indeed, into any shop shall be available, and the necessary exactitude can hardly be secured except on sales by dead weight. (*The National Food Journal*, 27th March, 1918.)

THE following Order (No. 375), dated 27th March, 1918, has been made by the Food Controller :—

**The Pigs (Prices)
Order, 1918.**

1 (a) Where a person sells any live pig otherwise than by dead weight, the maximum price shall be at the rate of 21s. per score of the live weight.

(b) Where a person sells any live pig by dead weight or sells any dead pig, the maximum price shall, if the offals are included in the sale, be at the rate of 28s. per score of the dead weight, and if the offals are not included in the sale shall be at the rate of 26s. 9d. per score of the dead weight.

2. (a) Where a live pig is sold otherwise than by dead weight, its weight for the purposes of this Order shall be its weight as ascertained at the time of sale by the live-stock auctioneer engaged in the sale or the market authority in whose market the pig is sold or as ascertained at any time after sale by a person authorised in that behalf by the Food Controller or a Food Committee; or if not so ascertained its weight at the place of slaughter.

Any directions given by any such live-stock auctioneer, market authority or other person with a view to the weighing of a pig for the purposes of this Order shall be duly complied with by all persons concerned.

(b) Where a pig, live or dead, is sold by dead weight, the dead weight of the pig shall for the purposes of Clause 1 of this Order be the weight of the dressed carcass excluding the weight of the offals.

3. Every person who in the course of his business buys any pigs and slaughters or causes to be slaughtered such pigs for the purpose of his business shall keep accurate records showing the prices paid for such pigs, and such other particulars as are necessary to show whether or not the provisions of this Order are being complied with, and shall make such returns as to his business as the Food Controller or a Food Committee may from time to time require. All such records and relevant documents shall be open to the inspection of any person authorised by the Food Controller or a Food Committee.

4. A person shall not sell or offer or expose for sale or buy or agree to buy any pig, live or dead, at a price exceeding the price applicable under the Order, or in connection with the sale or disposition or proposed sale or disposition of any pig enter or offer to enter into any artificial or fictitious transaction or make or demand any unreasonable charge.

5. The foregoing provisions of this Order shall not apply to—

- (a) boars or pedigree sows bought and sold specifically for breeding purposes;
- (b) breeding sows; and
- (c) pigs weighing at the time of sale less than 80 lb. live weight.

6. (a) No person shall sell or buy or offer to buy for slaughter any pig weighing at the time of sale or offer for sale less than 112 lb. live weight.

(b) Until the contrary be proved, a pig shall be deemed to have been sold and bought for slaughter if it be slaughtered within 28 days of the sale.

(c) This Clause shall not apply to any sale or purchase for slaughter of a pig weighing less than 112 lb. weight, where slaughter is for any exceptional reason or purpose authorised by a Live Stock Commissioner or his representative, or by any officer of the Board of Agriculture and Fisheries, or the Board of Agriculture for Scotland, or the Department of Agriculture and Technical Instruction for Ireland.

NOTE.—This Order revokes the Pigs (Maximum Prices) Order, 1917, and the licences thereunder, dated 20th November, 1917, and 16th December, 1917. (Nos. 1124, 1193 and 1248 of 1917.)*

In reply to a question in the House of Commons as to the amount of the present production of milk in England, Scotland and Wales,

Census of Cows and Heifers.

Mr. Clynes said that the only available statistics were those obtained by means of the various censuses taken by the Ministry of Food and the Board of Agriculture, but, though the number of cows could be given, it was not possible to give exact figures as to milk production, since the average yield per cow was unknown, and there were no figures to show the proportion of animals calving in any season of the year. The census figures were as follows:—

1. Census of 2nd December, 1917 (joint by Ministry of Food and Board of Agriculture), showed:—

Dairy Cattle only.

	<i>Cows and Heifers in Milk.</i>	<i>Cows and Heifers in Calf.</i>	<i>Other Breeding and Store Cattle 2 years and over.</i>
England and Wales	1,553,948	1,028,184	370,914
Scotland	239,317	210,794	47,373
Total ..	1,793,265	1,238,978	418,287
Grand Total	2,906,596		

It was estimated on 2nd December, 1917, by producers that they would sell (not produce) during three following months 125,801,646 imperial gallons.

2. Census by Board of Agriculture, 4th June, 1917.

	<i>Cows and Heifers in Milk</i>	<i>Cows in Calf but Dry.</i>	<i>Heifers in Calf with First Calf.</i>
England and Wales	1,831,443	271,537	361,814
Scotland	347,000	45,000	50,000
Total ..	2,178,443	316,537	411,814
Grand Total	2,906,794		

3. Census taken at request of War Office through Police, 21st April, 1917.

	<i>Cows and Heifers in Milk.</i>	<i>Cows in Calf but Dry.</i>	<i>Heifers in Calf with First Calf.</i>
England and Wales	1,735,328	365,700	421,508
Scotland	314,000	125,000	
Total ..	2,049,328	912,208	
Grand Total	2,961,536		

* See this *Journal* for 1917, pp. 924, 1031, and 1147.

On 1st March, 1918, the product of not more than 57,364 cows was being used for the manufacture of condensed milk. The amount of milk converted into dried milk during the six months ending 31st December, 1917, was not less than 4,713,118 gal., while during the six months ending 30th January, 1917, it was not less than 2,648,961 gal. The amount of milk used by Nestlé's in the manufacture of condensed milk in the six months ending 30th June, 1917, was 11,369,081 gal., and in the six months ending 31st December, 1917, 13,705,369 gal. (*The National Food Journal*, 27th March, 1918.)

PROPOSALS are under consideration for an extensive scheme for the rationing of all live stock through priority certificates. Pending the completion of the scheme the Food Controller has decided to extend to certain other classes of live stock the existing system of priority certificates under the Cattle Feeding Stuffs

**Priority Supplies
for Live Stock.**

(Priority Supply) Order, 1918,* which are now granted only to dairy cattle in milk. These additional classes and the maximum quantities of feeding stuffs under the certificates are : calves under 6 months old ($\frac{1}{2}$ lb. per day), horses which are maintained and used for agricultural purposes (10 lb. per day), breeding sows (4 lb. per day), and store pigs ($1\frac{1}{2}$ lb. per day).

In granting certificates the amount of feeding stuffs in the possession of the applicant will be taken into consideration, and in the case of sows and pigs no guarantee can be given that certificates can be granted for a supply during the summer months. The necessary forms of application for these certificates can be obtained from the Live Stock Commissioner for the area in which the applicant resides. (*The National Food Journal*, 27th March, 1918.)

THE Food Controller, by an Order (No. 281), dated 8th March, 1918, authorises, in addition to the dealing permitted by the above Order, the following dealings in milk :—

**The Milk
(Registration of
Dealers) Order, 1918.**

- (a) A sale in bulk by a producer who is not registered as a retail dealer under the above Order of less than 17 gal. if such sale comprises substantially the whole of the output of the producer ;
- (b) A sale by a person licensed to deal in milk by wholesale of any quantity of milk to a registered retail dealer in milk ;
- (c) An accommodation sale by a person licensed to deal in milk by wholesale or by a registered retail dealer in milk to any other person so licensed or registered.

AN Order (No. 296), dated 8th March, 1918, has been made by the Food Controller, including the following Clauses :—

1. *Maximum Prices.*—No person shall directly or indirectly sell or offer for sale or buy or offer to buy milk at prices exceeding the maximum prices provided by or in pursuance of this Order.

* See this *Journal*, February, 1918, p. 1307.

2. *Retail Maximum Prices.*—Until otherwise determined pursuant to this Order the maximum price applicable on the occasion of a retail sale of milk shall be—

- (a) For milk delivered during the month of April, 1918, at the rate of 2s. 8d. per imperial gal., for milk delivered during the months of May, June and July, 1918, at the rate of 2s. per imperial gal., and thereafter until the end of September, 1918, at the rate of 2s. 4d. per imperial gal. ;
- (b) Where at the request of the buyer the milk is required to be delivered in bottles, and is so delivered to the buyer's premises, an addition may be made to the foregoing prices at the rate of 1d. per qt., provided the milk is bottled under proper sanitary conditions at or before reaching the seller's premises ;
- (c) The foregoing prices shall include all charges for delivery, but it shall be permissible for a Food Committee for any area, from time to time, subject to the provisions of this Order, to fix for all or any of the milk sold within their area and not delivered to the purchaser's premises, a rate different from the rate for the time being applicable to milk which is so delivered.

3. *Wholesale Sales by Producers.*—(a) Where milk is sold wholesale by or on behalf of the producer the maximum price chargeable for milk delivered during the months mentioned in the first column of the following table shall be at the rate per imperial gal. set opposite the same in the second and third columns thereof :—

Month of 1918 in which Delivery takes place.	Rate per Imperial Gal. for Delivery in England or Wales.	Rate per Imperial Gal. for Delivery in Scotland.
	<i>s. d.</i>	<i>s. d.</i>
April	1 8	1 8
May	1 0	1 2
June	1 0	1 0
July	1 2	1 0
August	1 3	1 2
September	1 3	1 4

together in each case with a sum equal to the net amount of charges for railway transport actually incurred by the seller. Provided that the Food Controller may by notice under this Order fix as respects any area such higher prices as he may deem to be just when in his opinion it is proper so to do having regard to cost of production.

(b) The rates applicable under Sub-clause (a) of this Clause are fixed on the basis that the milk is delivered at the seller's expense to the buyer's premises or (at the option of the seller) to the buyer's railway station, and that in the latter case all charges for transport beyond the buyer's railway station are borne by the buyer. Where milk is not sold on this basis a corresponding adjustment shall be made in the rates, and for this purpose the cost of delivery to the buyer's premises or the seller's railway station shall be reckoned at a sum not less than a sum at the rate of $\frac{1}{4}$ d. per gal.

(c) No additional charges may be made for the provision of churns or other vessels.

4. *Wholesale Sales by Persons other than Producers.*—Where milk is sold wholesale by or on behalf of any person other than the producer the maximum prices chargeable shall, until otherwise determined pursuant to this Order, be as follows :—

- (a) In the case of milk delivered by the producer to or for the account of the buyer in accordance with the directions of the seller the rate shall, until the end of September, 1918, be $\frac{1}{2}$ d. per imperial gal. higher than the rate (not exceeding the maximum price) payable therefor to the producer by the seller.
- (b) In the case of milk not so delivered, the rate shall be in accordance with the following table :—

Month of 1918 in which Delivery takes place.	Delivery in England, Wales and Scotland.	
	*Rate per Imperial Gal. when Delivery is made to Buyer's Railway Station.	Rate per Imperial Gal. when Delivery is made to Buyer's Premises.
	s. d.	s. d.
April	*1 10	2 0 $\frac{1}{2}$
May	*1 2	1 4 $\frac{1}{2}$
June	*1 2	1 4 $\frac{1}{2}$
July	*1 2	1 4 $\frac{1}{2}$
August	*1 6	1 8 $\frac{1}{2}$
September	*1 6	1 8 $\frac{1}{2}$

* In addition to the railway charges paid by the seller for transportation from the seller's station to the buyer's station.

- (c) The rates mentioned in Sub-clause (b) are fixed upon the basis that the cost of providing churns or other vessels is borne by the seller ; and where milk is not sold on this basis, then the rate shall be ascertained by deducting from the rate applicable under such Sub-clause the sum of $\frac{1}{2}$ d. per imperial gal.
- (d) Except in the cases to which Sub-clause (a) of this Clause applies no milk shall be sold wholesale by or on behalf of a person other than the producer of the milk sold except upon the terms that the milk is to be delivered by or at the expense of the seller to the buyer's premises or the buyer's railway station.

5. *Power to Vary Maximum Prices.*—A Food Committee may except in the case of wholesale sales by or on behalf of producers, from time to time by resolution, vary the maximum price for milk delivered within their area or any part of such area but :

- (a) Every such resolution shall be reported to the Food Controller within five days and shall not take effect until three days after the same has been sanctioned by the Food Controller, and
- (b) Every resolution of a Food Committee under this Clause shall be subject at any time to review by the Food Controller, and shall be withdrawn or varied as he may direct.

6. (a) *Price to Establishments.*—Where milk is sold to an establishment as herein defined by any person (whether he be the producer of the milk sold or not) in a quantity of not less than 17 imperial gal., to be delivered in any one day, the maximum price (including charges for delivery to the buyer's premises) shall be whichever shall be less, namely :—

- (i.) 2d. per imperial gal. higher than the maximum price chargeable in the district in which the establishment is situate for milk delivered to the buyer's premises on a sale by wholesale by a person other than a producer ; or
- (ii.) The maximum retail price for the time being in force in such district.

(b) Any other sale to an establishment shall for the purposes of this Order be deemed to be a retail sale, and the maximum price shall be determined accordingly.

(c) "An establishment" for the purposes of this Order shall mean a public or private hospital, sanatorium, convalescent or nursing home, workhouse, infirmary, asylum, corporation, or company not established for purposes of trading or profit, a religious or charitable community, a residential school or college, and a canteen.

(d) A Food Committee shall have power with the consent of the Food Controller :—

- (i.) to apply the provisions of this Clause whether with or without modifications to a sale of milk to any body of persons^s which, in the opinion of the Committee, should be treated^d as an establishment as defined ;
- (ii.) to vary the provisions of this Clause in its application to any establishment.

7. *Small Wholesale Sales.*—Where a person who sells milk from a retail shop sells from such shop milk to a person buying for re-sale, the maximum price shall as to the milk so sold on any day be 2d. per gal. less than the maximum price applicable to sales of milk by retail in the area in which such shop is situate, if the quantity sold on that day to such person does not exceed 8 imperial gallons.

Milk to be Sold Retail by Measure.—No milk shall be sold or offered for sale by retail otherwise than by imperial measure.

Additions of Colouring Matter Prohibited.—No colouring matter shall be added to milk or cream intended for sale, and no milk or cream to which any colouring matter has been added shall knowingly be sold, or offered or exposed for sale.

10. *Addition of Water Prohibited.*—No water shall be added to milk intended for sale, and no milk to which any water has been added shall knowingly be sold, or offered or exposed for sale.

11. *Cans and Bottles.*—No person may use for the purpose of his trade or business any milk can, milk churn or milk bottle which bears the name or trade name or the trade mark or trade device of some person other than himself or his employer, except with the consent of such person.

12. *Artificial Transaction.*—No person shall, in connection with the sale or disposition or proposed sale or disposition of any milk, enter or offer to enter into any fictitious or artificial transaction or make or demand any unreasonable charge.

13. *Powers of Food Committees.*—A Food Committee may, subject to the consent of the Food Controller,

- (a) buy milk from any person and sell milk so bought at a price estimated to cover at least the cost of purchasing and distributing such milk; and
- (b) make arrangements as to the distribution of milk in their area.

14. (a) A Food Committee may

- (i.) direct any person delivering milk in their area to deliver such milk to any consumer or class of consumers in priority to any other person in their area; and
- (ii.) direct any person selling milk by retail within their area to deliver in that area only with such parts thereof as the Committee may prescribe; and
- (iii.) with the consent of the Food Controller give directions in their area for securing the purity, cleanliness and wholesomeness of milk, provided that any directions so given shall not relieve local authorities of their powers and duties under existing statutory provisions in regard to milk, or relieve cowkeepers, dairymen, purveyors of milk or occupiers of milk shops from their obligations under any such provisions.

(b) Every person to whom any direction is given under the powers conferred by this Clause shall comply with such directions.

16. *Contracts.*—Where any contract subsisting on the 1st April, 1918, for the sale of milk provides for the payment of a price in excess of the maximum price fixed by this Order applicable on the occasion of such a sale, the contract, unless otherwise determined by the Food Controller, shall be avoided so far as concerns milk which is to be delivered on or after that date.

17. The provisions of this Order relating to prices shall not apply to

- (a) milk sold for consumption on the premises of the seller, or
- (b) condensed milk, dried milk or milk preparations.

19. *Revocation.*—The Milk Order, 1917,* and the Price of Milk Order, No. 2, 1917, and the Milk (Amendment) Order, 1917, are hereby revoked as on the date when this Order comes into force, but without prejudice to any proceedings in respect of any previous contravention thereof.

The Order came into force on the 1st April, 1918, and extends only to Great Britain.

THE Food Controller, by an Order (No. 370), dated 25th March, 1918, has made the following Amendment to the Principal Order, No.

1186 of 1917:—†

**Order Amending
the Food
Control Committees
(Milk Requisition)
Order, 1917.**

1. Clause 2 of the Principal Order is hereby revoked and the following Clause is substituted:—

“2. A Food Committee shall agree to pay in respect of milk requisitioned under this Order the maximum price payable to a producer under any Order of the Food Controller for the time being in force and applicable to such producer.”

* See this *Journal* for September, 1917, p. 680.

† See this *Journal*, December, 1917, p. 1029.

THE Food Controller, by an Order (No. 386), dated 28th March, 1918, has made the following Amendment to the Principal Order, No. 1,105 of 1917* :—

**Order Amending
the British Cheese
Order, 1917.**

1. The Schedule to this Order shall be substituted for the Schedule to the Principal Order, which is hereby revoked.

2. The following Clauses shall be inserted after Clause 7 of the Principal Order :—

" 7. A. The provisions of Clause 7 of this Order shall not apply in the case of cheese delivered by or on behalf of the maker thereof on or after the 1st April, 1918, and the following provisions shall have effect as regards such cheese :—

" (a) The maker of any cheese (other than cheese of the Caerphilly, Wensleydale, Stilton and 'Small Holder' types) shall cause the same to be indelibly marked immediately after it is made with the date of its manufacture.

" (b) No addition shall be made to the price of any such cheese to compensate for shrinkage.

" 7. B. For the purposes of Clause 7 of this Order, no time after March 31st, 1918, shall be taken into account as part of a period of 14 days."

The Schedule.

Variety of Cheeses.	First-hand Prices for Delivery until 31st March, 1918, inclusive.	
	s.	d.
Wensleydale and similar makes ripened	1	7 per lb.
Stilton, ripened	1	7 "
Any whole milk cheese not exceeding 2 lb. weight, uncut	1	6 "
Caerphilly	129	0 per cwt. of 112 lb.
All other whole milk cheese	142	0 " "
Partially skimmed (British)	125	0 " "

B. FIRST-HAND PRICES FOR DELIVERY.

	Between 1st April, 1918, and 30th April, 1918, inclusive.	On and after 1st May, 1918, until further notice.
	s.	d.
Caerphilly, whole milk	1 4½ per lb.	1 2 per lb.
" Partially skimmed	1 3 "	1 0½ "
" Wholly skimmed	1 1½ "	0 11 "

* See this *Journal* for November, 1917, p. 910.

C. FIRST-HAND PRICES FOR DELIVERY.

	Between 1st April, 1918, and 31st May, 1918, inclusive.	On and after 1st June, 1918, until further notice.
	s. d.	s. d.
Ripened Stilton and Wensleydale (blue) ..	1 7 per lb.	1 7 per lb.
Dorset, Hand skimmed blue	1 4½ "	1 2 "
„ Separated blue	1 3 "	1 0½ "
„ White	1 1½ "	0 11 "
All other whole milk cheese	1 6 "	1 3½ "
„ partially skimmed cheese	1 3 "	1 0½ "
„ wholly skimmed cheese	1 1½ "	0 11 "

In all cases prices are *ex* Factory or *ex* Farm.

All these prices are subject to the following terms :—

For cash within seven days—2d. in the £ discount.

„ „ one month—1d. „ „

AN Order, (No. 387) dated 28th March, 1918, has been made by the Food Controller to the following effect :—

**The Sugar
(Domestic Preserving)
Order, 1918.**

1. When any person receives any sugar issued by the Royal Commission on the Sugar Supply (hereinafter called the Sugar Commission) for the purpose of the preserving of fruit grown by the preserver, such person shall not dispose of or deal with such sugar so as to divert the same to any other purpose or use the same except for the purpose of preserving fruit grown by him.

2. On any sale of any such sugar the vendor shall on the invoice or package clearly state that the sugar may be used only for the preserving of fruit grown by the preserver.

3. Where the invoice relating to or the package containing any sugar bears a statement to the effect that the same may be used only for the preserving of fruit grown by the preserver the sugar shall be deemed to have been issued by the Sugar Commission for the purpose stated.

4. (a) No retailer shall sell or dispose of any sugar issued by the Sugar Commission for the purpose of the preserving of fruit grown by the preserver except to a person named in and to the amount authorised by a permit issued by or under the authority of the Food Controller or the Sugar Commission.

(b) Every retailer shall in respect of such sugar comply with such directions as the Food Controller or the Sugar Commission may give from time to time.

5. Any person who shall have acquired any such sugar and who for any cause is thereafter unable to use or fails to use the same for the purpose for which it was issued shall give notice of the fact forthwith to the Food Committee, and shall hold such sugar at the disposal of the Committee.

6. Every person dealing with any such sugar shall keep records of the persons to whom such sugar was supplied and of the quantities supplied to them and the dates upon which supplies were made, and such records shall at all times be open to the inspection of any person authorised by the Food Controller or the Food Committee.

7. A person shall not—

- (a) Acquire or attempt to acquire or apply for any such sugar except for the purpose for which the same may be issued ;
- (b) Make or connive at the making of any false statement on any application or declaration to be made in connection with such sugar ;
- (c) Forge or alter any permit issued for the purposes of this Order ;
- (d) Obtain or attempt to obtain any such sugar on a permit issued for the purposes of this Order where the application therefor contained a statement false in any material particular ;
- (e) Fail to comply with any conditions subject to which any permit under this Order is granted to him ; or
- (f) Personate or falsely represent himself to be a person to whom any such permit has been issued or applies.

Note.—This Order revokes the Sugar (Domestic Preserving) Order, 1917, and shall not apply to Ireland.

For the purpose of the Sugar for Jam-making Distribution Scheme, 1918, "soft fruits" shall be taken to mean any fruits normally ready for preserving before the end of July, and in this category rhubarb may be included.

**Sugar for
Jam-Making.**

"Hard fruits" shall be taken to mean any fruits ready for preserving after 31st July. Pumpkins and other vegetables are not to be included in either class, but marrows may be included at the discretion of the Food Control Committee in any district where these are usually preserved. (*National Food Journal*, 10th April, 1918.)

AN Order (No. 294), dated 11th March, 1918, has been made by the Food Controller to the effect that :—

**The Appointment
of Arbitrators
Order, 1918.**

1. Each of the Orders mentioned in the first column of the schedule is hereby amended by the substitution for the Clause of such Order mentioned in the second column of such Schedule of the following Clause :—

"The Arbitrator to determine in default of agreement the compensation to be paid for any article requisitioned under this Order shall be appointed by the Lord Chancellor of Great Britain in England, by the Lord President of the Court of Session in Scotland, and by the Lord Chief Justice of Ireland in Ireland."

2. Copies of the Orders mentioned in the Schedule hereafter to be printed under authority of His Majesty's Stationery Office shall be

printed with the substitutions provided for by this Order, and such Orders shall hereafter take effect as if they had been originally made with such substitutions.

SCHEDULE.

Title of Order. I.	Clauses. 2.
The Barley (Requisition) Order, 1917	Clause 5.
The Cheese (Requisition) Order, 1917	Clause 4.
The Currants and Sultanas (Requisition) Order, 1917	Clause 3.

THE following Notice was issued by the Agricultural Wages Board on the 3rd April, 1918 :—

**The Committee of
Inquiry on the
Cost of Living
for Farmers and
Market Gardeners.**

The Committee appointed by the Agricultural Wages Board to inquire into the financial results of farming and market-gardening and the cost of living as affecting rural workers, under present conditions, consists of six members of the Wages Board and three co-opted members. It is constituted as follows : Sir Henry Rew (*Chairman*), Sir W. J. Ashley, Mr. George Dallas, Mr. W. Gillies, Mr. F. Ivo Neame, Mr. C. S. Orwin, Mr. R. R. Robbins, Professor W. Somerville and Mr. R. B. Walker. Mr. A. W. Ashby and Captain Proby have been appointed joint secretaries to the Committee.

THE following Notice was published in March by the Government of the Commonwealth of Australia :—

**Farming for Soldiers:
Opportunities in
Australia for British
and Allied Troops.**

Australia has wasted no time in the preparation of comprehensive land settlement schemes for soldiers. Within a few months of the outbreak of War, the problem of placing the men on suitable areas after their service ended was tackled by public men and the merits of various schemes inquired into. The Commonwealth Government intends to set aside a total of £32,000,000 for repatriation, and various State schemes are already in operation.

British soldiers and sailors will be interested in the scheme lately adopted by the Government of Queensland. Land comprising 234,300 acres has already been set aside, and negotiations are in progress for the resumption of other areas. Within the meaning of the " Discharged Soldiers Settlement Act," which deals with the subject, a " discharged soldier " not only includes members of the Australian Imperial Forces but any person who has joined the forces of the United Kingdom during the War and who has received an honourable discharge.

The terms may be extended so as to include members of His Majesty's forces during the present War from any part of the British Empire or

members of the allied forces who have received their discharge before their arrival in Queensland. The term also includes the dependants to any such soldier, in the event of his death before he receives his discharge, or within a period of twelve months after he has received it.

Portions of the land set aside have already been cleared and planted, and a varied assortment of farming pursuits are recommended, such as pineapple growing, poultry raising, beekeeping, apple, pear, peach and plum orchards, dairy and sugar-cane farms. Liberal financial assistance will be given to settlers, particularly in the first years of their occupation.

THE following Letter (No. 102 L. 3), dated 20th March, 1918, has been addressed to Secretaries and Inspectors of the Women's Land Army by the Food Production Department of the Board :—

**Registration of the
Names of Women
Desirous of Taking Up
Farm Work as a
Profession.**

DEAR MADAM,—When an appeal was made by the Government last March for women to come forward and work on the land, certain benefits were offered in regard to training, outfit and maintenance. At the same time it was announced that selected members of the Women's Land Army who wish, after the war, to farm on their own account and to form themselves into groups for this purpose, will be separately registered, and every effort will be made to secure for them special facilities for settlement on the land either at home or in the Dominions overseas.

In order to be ready for any specific plan which may be formulated after the war, the names of women desiring to take up farm work as a profession should be recorded. I would ask you therefore to make a careful note of any woman who expresses a wish to farm either in Great Britain or overseas, with her name, address, age, length of training and experience, qualifications, character, and to send the same to this Department for future reference.

Even before the end of the war it is possible that some scheme may be arranged to help women in this direction. A register of suitable names would be of much service.

Yours faithfully,

MERIEL L. TALBOT,

Director, Women's Branch.

THE following Notice has been issued by the Food Production Department of the Board :—

**The Land Women
and Billeting.**

In view of various statements in the Press, the Food Production Department wish it to be understood that the question of billets for the Women's Land Army is well in hand. Through the Women's Organisation set up in every county suitable billets are found for the Land Army girls imported into a given district.

The billets are inspected, the local rate of payment ascertained, and every care is taken to ensure the well-being of the land workers.

Should cases arise where the County Organisers find insuperable difficulty in obtaining suitable lodgings for the workers, the Department will be able to exercise compulsory powers under the Civilian Billeting Act.

THE following Memorandum (No. 50 L. 1), dated 25th March, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Military Service
Act, 1918.**

In consequence of the passing of the above Act, fresh Regulations and Instructions (superceding all previous Regulations and Instructions), have been issued by the Local Government Board. Copies of these (R. 174 and R. 175), and of the covering letter (R. 173), are enclosed for your information.* Copies of the Act are not available for distribution.

So far as they affect men engaged in agriculture and allied trades, the alterations made in the Regulations and Instructions relate to the periods within which both unattested and attested men, whose certificates of exemption have ceased to be in force, may apply for the renewal of their exemptions.

Hitherto where a man's exemption had expired, an unattested man was entitled to apply for renewal before or within two weeks after the date on which his certificate ceased to be in force, and an attested man could apply for renewal within seven days of the date of the notice calling him up for service with the Colours.

Under the new Regulations and Instructions these periods of grace still hold good in the cases of men whose certificates have ceased to be in force before the 11th March, 1918, but *as regards both unattested and attested men, whose certificates cease to be in force after the 11th March, 1918, and application for renewal may be made before or within seven days after the date on which the certificate ceases to be in force.*

VOL. LII., Part 1, Agricultural Statistics, 1917, giving particulars of the Acreage and Livestock of England and Wales, with a Summary for the United Kingdom, has just been published. Copies of the Return may be obtained

**Acreage and Live
Stock Returns of
England and Wales.** from H.M. Stationery Office, price 3d. net., excluding postage.

In the Summary to the Return, Sir Henry Rew shows that from June, 1914 to June, 1917, there has been an increase in the acreage of arable cultivation to the extent of 330,000 acres, while the acreage under wheat, barley and oats during this period has risen to nearly one million acres; the greater part of this increase took place between June, 1915 and June, 1916. The area under wheat in 1917 was 1,918,485 acres, an increase of 6,277 acres on the 1916 area, barley 1,459,796 acres, an increase of 127,720 acres since 1916, and oats 2,258,909 acres, an increase of 174,235 acres since 1916. The announcement by the Government in February, 1917, of the guaranteed prices for wheat, oats and barley was too late in the season to affect the summer wheat crops, though probably the output of spring-sown crops was influenced by this offer.

In regard to permanent grass, the area during 1917 was 15,835,375 acres, or 187,608 acres less than in 1916. The total acreage under hay was 6,476,112 acres, a decrease of 112,575 acres on the 1916 area.

The other most noticeable features since 1914 are the increase in the area of potatoes by 170,000 acres, mainly in Ireland; a decrease of nearly 11 per cent. in the area under beans; an increase of 16 per

* Not here printed.

cent. in the area under potatoes ; a decrease by more than 50 per cent. of the hop cultivation ; and a reduction by nearly 600,000 acres of clovers and " seeds."

As regards live stock generally the numbers up to June, 1917, were well maintained except for pigs, which show a loss of nearly 1,000,000, the number returned, viz., 1,918,541, being the lowest since 1880. Horses and cattle show a slight increase, while in the case of sheep a decrease is shown.

THE following Letter (No. 47/L. 2), dated 28th March, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Parasitic Mange
among Horses.**

SIR,—Owing to the prevalence of parasitic mange among horses, particularly in certain counties, I am directed to remind you of the great importance of notifying promptly to the Board of Agriculture and Fisheries, 4, Whitehall Place, S.W. 1, every outbreak, whether in the case of horses belonging to the Food Production Department, or of those loaned by the Army ; such notification should in every case be in the form of the specimen attached.

In the case of horses loaned by the Army, the Horse Officer should be careful to ascertain whether notification of the outbreak has already been transmitted by the Local Authority to the Command Headquarters to which the horse belongs. Where this information has already been transmitted this fact should be stated by the Horse Officer, together with any particulars he may be able to obtain as the result of the investigation by the Army Authorities.

Where, on the other hand, no such information has been furnished by the Local Authority to the Command Headquarters, the Horse Officer should also be careful to state this fact, and to see that the address of the Headquarters is accurately set out in his report.

I am, etc.,

(Signed) JOHN L. HUNTER, *Captain.*

For Director of Labour.

THE following letter (No. A. 763), dated 5th April, 1918, has been addressed to Local Authorities by the Board :—

Sheep-Scab.

SIR,—I am directed by the President of the Board of Agriculture and Fisheries to refer to the Circular Letter addressed to Local Authorities by the Board on the 16th March, 1917 (A. 303/C), calling attention to the importance of securing the double-dipping of all sheep which have been in contact with sheep concerned in an outbreak of sheep-scab, by the service of Notices (Forms C and E) under the Sheep-Scab Order of 1910, and I am to say that it would be of assistance to the Board if they could be furnished with information in each case showing the dates upon which the sheep referred to in these Notices have actually been dipped. It would appear that the most convenient method of obtaining this information would be through the Inspector of the Local Authority in whose presence the dippings were carried out, and who would as a rule be the Inspector who serves the Notice (Form F) withdrawing the Notice (Form C), as he would necessarily have this information before him at the time. The President would be obliged, therefore, if your Local Authority would be good enough to issue

directions to their Inspectors to add to the copies of Notices (Form F) forwarded to the Board the dates on which the two dippings of the sheep referred to in the relative Notices (Forms C and E) were carried out.

I am also to take this opportunity of reminding your Local Authority of the request to Local Authorities contained in the Board's Circular Letter of the 15th July, 1912 (A 211/C), to arrange that the name and address of the person on whom the Detention Notice (Form A) has been served under Article 2 of the Sheep-Scab Order of 1905 should be given on each copy of the Notice (Form C, E and F) in addition to the name and address of the person on whom the latter Notice is served. In many cases it is observed that this request is not complied with, and the Board would be glad if your Local Authority, in issuing the directions desired in the first paragraph of this letter, would at the same time add an instruction to meet their request under this head also.

I am, etc.,

(Signed) A. D. HALL,

Secretary.

THE Department of Agriculture of the Government of India have, under the Destructive Insects and Pests Act, 1914, placed the following restrictions on the importation of certain plants and seeds into British India :—

**Importation of
Plants and Certain
Seeds into British
India.**

(1) No plant may be imported into British India by means of letter or sample post.

(2) No plants except fruits and vegetables intended for consumption, no potatoes and no

sugar cane may be imported into British India by sea except after fumigation with hydrocyanic acid at one of the following "prescribed ports"—Bombay, Calcutta, Dhaneshkhodi, Karachi, Madras, Negapatam, Tuticorin and Rangoon.

This provision does not apply to plants imported under the special certificate of the Imperial Entomologist to the Government of India for experimental purposes.

(3) Potatoes imported into British India must be accompanied by a certificate from the consignor declaring the district and county of origin, and guaranteeing that no Wart Disease is known to exist on the land where the potatoes were grown; also by an official certificate that no case of Wart Disease of potatoes has been known to exist during the previous twelve months within five miles of the place of where the potatoes were grown. In the United Kingdom, the proper officer or authority for the issue of this certificate is the Board of Agriculture and Fisheries for England or the Board of Agriculture for Scotland; and the Department of Agriculture and Technical Instruction for Ireland.

THE following Rules for the disinfection of plants imported by sea into Calcutta have been issued by the Governor of Bengal in Council under the Destructive Insects and Pests Act,

**Importation of
Plants into Calcutta.**

of 1914.

(1) It shall be the duty of the Customs staff to conduct the operation of disinfection of plants on their entry at the port of Calcutta.

(2) The fumigation of such plants by hydrocyanic acid gas shall be in accordance with the instructions received from the Imperial Entomologist, Pusa.

AN Act entitled the Fungicides Act of 1916, regulating the sale of fungicides, insecticides and vermin and weed destroyers was passed by the Legislature of the Government of the Commonwealth of Australia in November, 1916, and contains the following main provisions:—

**An Act to
Regulate the Sale
of Fungicides, etc.,
in Australia.**

(1) The Governor-General in Council may by proclamation fix the standards as to the constituents of which any fungicide, insecticide, vermin destroyer or weed destroyer can be composed; and no one shall sell any article which is not in accordance with the standard so fixed and declared; otherwise he shall be deemed to have committed an offence under this Act.

(2) Every package containing any fungicide, insecticide, or vermin and weed destroyer must show a full statement of the component parts of its contents, and at the time of sale the seller must give the buyer an invoice or statement, containing the trade name or description of the article sold, and its component parts, with the percentage standard strength of each; and such invoice or statement shall operate as a warranty by the vendor of the accuracy of the facts therein stated.

The Act also provides, among other things, for the appointment of inspectors and the testing of samples of sales of fungicides, etc.

THE following is a list of Retail and Wholesale Maximum Prices of certain agricultural commodities fixed by the Food Controller (extracted from recent issues of the *National Food Journal*):—

RETAIL MAXIMUM PRICES.

Bacon and Ham—

Over actual cost to retailer 3d. per lb.

The profit may be averaged when a side of bacon is cut.

Beans, Coloured Haricot	5½d. per lb.
„ White Haricot	6d. „
„ Large Butter	8d. „
„ Japanese Daifuku	8d. „

Butter, a rate not exceeding actual cost as defined by the Order to the retailer by 2½d. per lb.
A charge may be made for credit and delivery, otherwise than by post or rail, not exceeding ½d. „
Government Butter 2s. 6d. „

Cheese, an addition to actual cost to the retailer as defined by the Order, not exceeding 2½d. per lb.
(This price includes delivery and credit charges to the customer.)
Government Cheese 1s. 4d. „

Damaged Grain, Seeds, and Pulse—

For quantities not exceeding 7½ qr., add to whole sale prices 4s. per 480 lb.
For quantities of less than half a qr. 8s. „

Potatoes: Ware—

Sold by grower, quantities less than 1 cwt. 1d. per lb.

Sold by retailer, the following scale:—

Retailer's Buying Price per cwt. for Potatoes Delivered at the Place at which he usually Takes Delivery.	Highest Authorised Retail Selling Price over the Counter.		
	Per Stone of 14 lb. for Lots of 14 lb. or more.	Per Half Stone for Lots of 7 lb. or more, but less than 14 lb.	Per lb. for Lots of less than Half Stone.

Aberdare.—Evan Walters, cattle dealer, on sales of meat, £150 with £31 10s. costs. Nine summonses held over pending appeal.

Nottingham.—William Henry Mitchell, Bobbers Mill, on sales of milk with 48 per cent. added water and a 33 per cent. deficiency of fat, £25.

Stroud.—The Stroud Co-operative Society, on sales of margarine as butter, £15 5s., including costs.

Thames.—Four and three months' hard labour were the sentences pronounced on Lewis and Simon Marcus, Cecil Street, Mile End, for watering milk. Within a year the former had paid £100 in fines for this offence.—John McGown, Goldsmiths' Row, Shoreditch, on sales of milk with 90 per cent. deficiency of fat, £20.—Michael Samuels, Hoxton Street, on a similar offence, £10.

Great Missenden.—For letting a stack of wheat be damaged Alexander Axarlis, shipper, Guildford, was fined £50 and costs, and his bailiff, Albert Price, £10.

Stowmarket.—For milling wheat and barley contrary to the Flour and Bread Order (No. 2), 1917, and for failing to make returns, F. R. Cook and Co., Stow-Up-land, were fined £45 with 9 guineas costs.

Wakefield.—Having bought two cows otherwise than through a market, William Taylor, Smithies, Barnsley, was fined £40; and a similar penalty was imposed upon Fred Brooke, Alverthorpe, the purchasing dealer.

Rugeley.—John Ashmore, farmer, Hamstall Ridware, on sales of adulterated milk, £25 and 4 gs. costs.

South-Western.—Messrs. Aplin and Barrett, and the Western Counties Creameries, Ltd., on sales of butter, £15, with 5 gs. costs.

Milford Haven.—Fined £50 for selling milk with 55 per cent. of added water, John Davies, Thornton Dairy Farm, was also sentenced to three months' hard labour. He had carried some churns containing water only.

Lutterworth.—For feeding horses with barley, Rowland Nichols, farmer, Swinford, was fined £20, with costs. (*The National Food Journal*, 27th March and 10th April, 1918.)

MISCELLANEOUS NOTES.

THE *International Crop Report and Agricultural Statistics* for March, 1918, issued by the International Institute of Agriculture, contains estimates of the production of cereal crops in the Northern Hemisphere. The countries in respect of which it is possible to give forecasts are as follows:—In *Europe*—

Notes on Crop Prospects Abroad.

Denmark, Spain, France, Great Britain, Ireland, Italy, Luxemburg, Norway, Netherlands, Sweden, Switzerland; in *America*—Canada, United States; in *Asia*—British India, Japan; in *Africa*—Algeria, Egypt, Tunis.

Wheat.—The total production in the above-mentioned countries is estimated to amount to 234,094,000 qr. in 1917, against 242,173,000 qr. in 1916, a decrease of 3·3 per cent., while the area sown was smaller by 5·8 per cent.

Rye.—In the above-mentioned countries in Europe and America, except Great Britain, the yield is placed at 18,704,000 qr. in 1917, against 19,396,000 qr. in 1916, a decrease of 3·6 per cent., but the area sown was larger by 7·1 per cent.

Barley.—The production in the specified countries, excluding British India, is estimated at 76,094,000 qr. in 1917, against 73,122,000 qr. in 1916, or an increase of 4·1 per cent., the area sown being greater by 5·3 per cent.

Oats.—The total yield in the specified countries, with the exception of British India and Egypt, is placed at 281,578,000 qr. in 1917, or an increase of 12·4 per cent. compared with 1916, when it amounted to 250,502,000 qr., while the area sown showed an increase of 6·8 per cent.

Maize.—The total production in Spain, France, Italy, Switzerland, Canada, United States and Japan is estimated to amount to 385,286,000 qr. in 1917, against 317,312,000 qr. in 1916, an increase of 21·4 per cent., the area sown being greater by 12·4 per cent.

Sowing of Winter Cereals in the Northern Hemisphere.—The areas estimated to have been sown with winter *wheat* in 1917-18, compared

with the areas sown during the corresponding period of 1916-17, expressed as percentages, are as follows:—Denmark, 102, Spain 95, France 107, England and Wales 115, Scotland 122, Luxemburg 105, Canada 96, United States 105, British India 110, Japan 118, Tunis 113; with *rye*:—Denmark 118, Spain 108, France 96, England and Wales 103, Luxemburg 95, United States 145; with *barley*:—Spain 100, France 92, England and Wales 100, Japan 99, Tunis 111; with *oats*:—Spain 115, France 106, England and Wales 100, Tunis 120

France.—According to a report published by the Ministry of Agriculture on 22nd March, the condition of the crops was as follows (figures for March, 1917, in brackets):—Winter wheat, 72 (59); winter barley, 71 (60); winter oats, 71 (57); and rye, 73 (64). (80 = good, 60 = fairly good, 50 = passable.) (*Broomhall's Corn Trade News*, 23rd March, 1918.)

Canada.—According to a report, dated 5th April, received from the High Commissioner for Canada, the weather conditions in Western Canada are very favourable for sowing and preparation of the land, and this work is stated to be three weeks in advance of last year. It is estimated that over 12,000,000 bush. of wheat still remain in farmers' hands in Western Canada.

United States.—According to the official report issued on the 4th April, the autumn-sown wheat crop has practically everywhere improved during March owing to the favourable weather which has generally prevailed. (*Broomhall's Corn Trade News*, 5th April, 1918.)

According to a report issued on the 8th April by the Statistician of the Department of Agriculture, the average condition of winter wheat and rye in the United States on the 1st April was estimated as follows:—Wheat, 78·6 per cent., compared with 79·6 per cent. in December last, and 63·4 per cent. a year ago; and rye, 85·8 per cent., compared with 84·1 per cent. in December and 86·0 per cent. a year ago. The area is estimated as follows:—Wheat, 42,170,000 acres compared with 40,534,000 acres last year; and rye, 6,119,000 acres compared with 4,480,000 acres; whilst from present appearances the yield of wheat is forecasted at 560,000,000 bush. against 418,000,000 bush. last year, and rye at 86,000,000 bush. compared with 60,000,000 bush. (*Broomhall's Corn Trade News*, 8th April, 1918.)

India.—According to the second general forecast issued on 15th March, the total area sown with wheat is 34,469,000 acres compared with 32,940,000 acres, the final estimate of last year. The second official forecast of the linseed acreage is 2,932,000 acres which compares with 2,858,000 acres the final estimate in 1916-17. (*Broomhall's Corn Trade News*, 18th and 21st March, 1918.)

Australia.—The total production of the wheat crop of the Commonwealth for 1917-18 is estimated at 121,679,153 bush. as compared with an actual yield of 152,565,689 bush. in 1916-17. Each of the States, with the exception of New South Wales and Tasmania, shows a diminished yield this season. (*Broomhall's Corn Trade News*, 4th April, 1918.)

According to reports from the Weather Observers of the Commonwealth Meteorology Department, the weather of December was general fairly favourable to agriculture. The yield of wheat appears to be only fair on the whole, and in some districts damage by rust is reported. Grass was as a rule plentiful, and live stock are generally in good condition.

THE Crop Reporters of the Board, in reporting on agricultural conditions in England and Wales, state that the weather of March was everywhere most favourable for all farming operations.

**Agricultural
Conditions in
England and Wales
on 1st April.**

Wheat is generally very satisfactory, being strong and healthy, and quite promising, although here and there the plant is occasionally thin, and a certain number of reports refer to damage by wireworm on newly-ploughed grass land. Other autumn-sown crops are also quite satisfactory.

Cultivation of the land for spring crops proceeded without interruption, the land working well; and much of the spring corn has now been sown under very favourable conditions. The early-sown crops have germinated satisfactorily. In the chief potato districts of the Fens and Lancashire, planting of this crop is in full swing. Elsewhere, some early potatoes only have been got in, and, generally speaking, the land is being rapidly prepared, but only a beginning has been made with the main crop. Work generally is very well forward for the time of year.

Seeds are generally healthy and vigorous, giving promise of a good crop; still, however, with the exception of the east and north-east of the country, where they are patchy, but here also there has been some improvement during the month.

Lambing has been general all over the country. The condition of the ewes is nearly everywhere described as only fairly good, owing to the shortage of artificial food; but the fall of lambs is everywhere satisfactory, and often good. The lambs themselves are reported as strong, and with the unusually favourable weather there has been little mortality, either among the ewes or lambs.

The supply of labour, especially skilled kinds, is still short, but with the assistance of soldiers, women, and German prisoners in many places, and with the very favourable weather allowing work to be continued throughout the month without a break, the situation has been much relieved, and, as mentioned above, work is well forward. In most parts of the country there was a general rise of wages at Lady-day.

The following local summaries give further details regarding agricultural labour in the different districts of England and Wales:—

Northumberland, Durham, Cumberland, and Westmorland.—The supply of labour is deficient, but owing to the fine March, work is well advanced.

Lancashire and Cheshire.—The supply of labour is deficient in most districts, and the scarcity will be more felt when potato-planting is general, but the fine weather has allowed work to get well forward.

Yorkshire.—The supply of skilled labour remains deficient. Soldiers and women have been of great assistance, and the position is generally better than expected. Temporary labour for special work is still difficult to obtain.

Shropshire and Stafford.—The supply of labour is very short, especially of casual labour, but, with the assistance of the military and women, and the very favourable weather during the month, work has been kept well forward.

Derby, Nottingham, Leicester, and Rutland.—The supply of labour is generally insufficient for the amount of work to be done, and it is anticipated that the shortage will be more keenly felt within the next few weeks. Soldiers, women, and German prisoners have done good work.

Lincoln and Norfolk.—The supply of labour is generally rather deficient. Casual labour is very scarce, but it is expected that women and soldiers will do most of the potato planting. Wages have been increased by 5s. a week in many districts.

Suffolk, Cambridge, and Huntingdon.—The supply of labour is still deficient in most districts, but the favourable weather has allowed farmers to get well ahead with the spring work.

Bedford, Northampton, and Warwick.—The supply of labour is deficient in certain districts, but, with the assistance of soldiers and women, the supply is elsewhere about sufficient for present needs. Carters are scarce, and wages in some places have gone up.

Buckingham, Oxford, and Berkshire.—Though skilled labour is deficient work is not backward, soldiers and women having done much to make up the deficiency.

Worcester, Hereford, and Gloucester.—The labour supply is generally deficient, especially as regards skilled men. Soldiers, women, and boys have been of great assistance, and work is fairly well in hand. Casual labour is almost unobtainable.

Cornwall, Devon, and Somerset.—The labour supply is everywhere very short, and, even with the assistance of soldiers, women, and German prisoners, farmers have difficulty in getting sufficient. Wages were increased by 3s. to 5s. per week at Lady-day in some districts, and there appears to be a general tendency in that direction.

Dorset, Wiltshire, and Hampshire.—The supply of labour, particularly skilled labour, is short, but much assistance has been given by women as well as soldiers.

Surrey, Kent, and Sussex.—The supply of skilled labour is short, but, with the assistance of women and soldiers, and favoured by the fine weather, farmers have been able to cope with the work. Wages tend to increase.

Essex, Hertford, and Middlesex.—Though the supply of labour is deficient, the shortage does not appear serious. Soldiers, women, and German prisoners have rendered good assistance.

North Wales.—Labour remains very short everywhere, but the favourable weather has somewhat eased the position by allowing work on the land to be continued through the month without a break. Casual labour is difficult to get in most districts.

Mid Wales.—Labour is everywhere very short, particularly as regards skilled workers. The help of soldiers and women, together with the exceptionally favourable weather has somewhat improved the position.

South Wales.—The supply of labour continues deficient. The favourable weather and the help of soldiers have somewhat eased the position, but casual labour, which will be needed for potato planting, is difficult to obtain.

THE following statement shows that according to the information in the possession of the Board on 1st April, 1918, certain diseases of animals existed in the countries specified :—

Austria (on 6th March).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Denmark (month of January).—Anthrax, Foot-and-Mouth Disease, Swine Erysipelas.

France (for the period 17th February—2nd March).—Anthrax, Black-leg, Foot-and-Mouth Disease, Glanders, Rabies, Sheep-pox, Sheep-scab, Swine Erysipelas, Swine Fever.

Germany (for the period 15th—28th February).—Foot-and-Mouth Disease, Glanders and Farcy, Swine Fever.

Holland (month of February).—Anthrax, Foot-rot, Swine Erysipelas.

Hungary (on the 6th March).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Italy (for the period 25th February—3rd March).—Anthrax, Black-leg, Foot-and-Mouth Disease (1,893 outbreaks), Rabies, Sheep-scab, Swine Fever, Tuberculosis.

Norway (month of January).—Anthrax.

Sweden (month of February).—Anthrax, Swine Fever.

Switzerland (for the period 18th—24th February).—Anthrax, Sheep-scab, Swine Fever.

No further returns have been received in respect of the following countries : Belgium, Bulgaria, Montenegro, Rumania, Russia, Serbia, Spain.

THE JOURNAL

OF THE

BOARD OF AGRICULTURE

Vol. XXV. No. 2.

MAY, 1918.

SOILING CROPS FOR DAIRY COWS.

OWING to the reduction in the area of grass land and the short supplies of concentrated foods, it will be necessary for dairy farmers to grow green crops for summer feeding if supplies of milk are to be fully maintained. The choice of these crops will be determined by local conditions, and it is obviously impossible to give advice which can be applied exactly to all parts of the country. The accompanying tables have, however, been drawn up as a rough guide, the dates given being applicable to average conditions in the Midlands of England. In the North of England the times of cutting, etc., will in most cases be about a fortnight later ; in the South, a week or two earlier.

From the list of crops given a succession of green food, from kale and rye in April to cabbages in November, can be provided. For the winter period the various root crops would be available ; their cultivation is so general that it has not been thought necessary to give details.

In some cases the same ground will carry two crops in the course of a year. For instance, land carrying autumn-sown kale and cleared by the end of April may be sown with spring oats and vetches (mixed). Rye may be followed by cabbages or maize ; oats and vetches by cabbages, rape or white turnips ; late-sown oats and vetches by thousand-headed kale or rye. In most cases these crops will only be regarded as supplementary to pasture, but to indicate the possibility of dairying even when very little grass is available a column has been included showing the number of days for which a herd of 10 cows could be maintained on the forage crop alone. The figures are based on the assumption that a cow receiving no grass would require 80 lb. of green food per day.

At the Harper Adams Agricultural College in 1917, 6·3 acres of soiling crops and 1·5 acres of seeds hay produced green keep for 10 cows from 25th May to 30th November, with the exception of 7 days in August when the cows were fed on

clover aftermath. The manured plots averaged in yield from 8 to 9 tons per acre; the unmanured plots 6.2 tons. The yield of milk per acre was 499 gal., and the field, in addition, produced 372 lb. per acre of live-weight increase in the sheep folded on the three kale plots which were taken after the fodder crops; also in April the field produced keep for 87 ewes and 102 lambs for 10 days.

TABLE I.—*Green Food, supplementary to Grass, required for the Maintenance of 100 Cows.*

		Green Food per Cow per Day.	Total Quantity Green Food for 100 Cows for Period.	Approximate Acreage of Crop Required.
Mid May to end of June.	100 acres of grass.	Mixed winter oats and vetches if droughty June.	—	3 acres.
1st to 15th July.	"	Mixed winter oats and vetches, 40 lb.	27 tons	3 "
15th July to 31st August.	"	Mixed spring oats and vetches or peas, 40 lb.	81 "	8 "
September and October.	"	Maize, cabbages, rape, 80 lb.	215 "	8 acres maize or cabbages (in ad- dition to rape or white turnips, which would fol- low oats and vetches as above).
November	—	Cabbages and rape, 80 lb.	108 "	4 acres cabbage (in addition to rape or white turnips as above).
December to March (inclu- sive).	—	Mangolds, 80 lb.	430 "	17 acres.
April ..	—	Mangolds, 40 lb. thousand-headed kale, 40 lb.	54 " 54 "	5 acres mangolds. 5 acres kale taken on land previous- ly cropped with oats and vetches.
1st to 15th May.	100 acres of grass.	Rye, 40 lb. ..	27 "	5 acres rye taken on land previous- ly cropped with oats and vetches.

So far as grass, green food and roots are concerned, the herd of 100 cows could thus be maintained on—

Pasture	100 acres grass.
Mangolds	22 acres.
Cabbages and maize	12 "
Winter oats and vetches ..	6 "
(followed by rape and kale.)	
Spring oats and vetches ..	8 "
(followed by kale and rye.)	50 acres arable (approx.).

TABLE II.
Suggested Cropping during Year.

Crop.	Time of Sowing.	Amount of Seed per Acre.	When Ready for Use.	Period in which Available.	Weight of Green Food per Acre under Good Average Conditions.	Number of Days for which 1 Acre might Keep 10 Cows (without Grazing).
Giant rye	August and September	150 to 180 lb.	End of April	May	6 or 7 tons	17 to 20 days.
Mixed winter oats and vetches.	September and October	120 lb. oats, 60 lb. vetches.	Beginning of June.	June and early July	9 or 10 tons*	25 to 28 days.*
Mixed spring oats and vetches or peas.	March and April	120 lb. oats, 60 lb. vetches, or 100 lb. field peas.	End of June	July and August	10 or 12 tons*	28 to 33 days.*
Cabbages (early)	Autumn, transplanted early in spring.	1 lb. seed 12,000 plants.	Beginning of August.	August and September.	20 tons	56 to 60 days.
Cabbages (Late Drumhead).	Autumn, transplanted in early summer.	1 lb. seed 10,000 plants.	End of Sept.	October, November and December.	25 to 30 tons	70 to 84 days.
Cabbages (early)	April and May	2 lb. seed	October	October and November.	20 to 25 tons	56 to 60 days.
Maize	End of May and beginning of June.	100 to 112 lb.	Beginning of September.	September and October.	20 tons	56 to 60 days.
Kale (marrowstem)	April and May	3-4 lb. in rows, or 5-6 lb. broadcast.	End of September.	" " "	15 tons	40 to 45 days.
White turnips	July	2-3 lb. in rows	November	November and December.	10 to 15 tons	28 to 40 days.
Rape	July and early August	5-6 lb. broadcast	End of October	November	7 to 12 tons	20 to 30 days.
Kale (thousand-headed).	" "	" "	March	March and April	10 to 15 tons	28 to 40 days.

* Any surplus not required for soiling should be made into hay or silage.

The cows were turned out daily into a small paddock for exercise, but the amount of grass they could obtain in this way was negligible. In addition to the green food, which averaged 80 lb. a day, they received 4 lb. of cake per head daily.

On most farms the grass on the farm would be almost adequate to maintain the maximum flow of milk from the middle of May to the end of June. During July and August half-rations of supplementary green forage would be required, and only from September onwards would the green crops have to provide the greater part of the raw material for milk production.

The scheme of cropping and management (Table II.) may be taken as an illustration of the possibilities of this system. It is assumed that the land is of good average quality, that 100 cows have to be provided for, and that the total area of grazing is 100 acres, no aftermath being available. In a good grass year the amount of supplementary green food required would be much less than that allowed, but in order to safeguard against drought it would be advisable to produce the quantities stated. Any surplus could be stored or made into hay or silage, or utilised for other stock, as the case may be.

This article is also being issued as Food Production Leaflet No. 37. Copies free on application.

THE STOCK-CARRYING CAPACITY OF GRASS AND TILLAGE LAND.

In Food Production Leaflet No. 7, *Maintenance of Supplies of Hay and other Fodder Crops*,* an example was given to show that in the case of a dairy farm the area of arable land could be greatly increased and grain grown for sale without diminishing the stock-carrying capacity of the farm. In the following illustration it is shown how on a stock-rearing farm, the area under tillage may be trebled in three years without causing any decrease in the output of stock.

The case is assumed of a west-country stock-rearing farm of 300 acres, of which 50 acres are under the plough and worked on a four-course shift; 50 acres are good feeding land, and the remaining 200 acres are grass of moderate quality, much of which is on a well-drained free-working loam and has been laid down within the last 20 or 30 years. The present system of working would generally be somewhat as follows:—

A herd of about 20 cows would be kept; all the home-bred calves would be reared, and, in addition, an equal number of calves

* Printed in this *Journal*, September, 1917, p. 649.

would be bought. A few of the best heifers would be retained to take the place of draft cows sold either as fat or calving cows; the remainder of the calves would be reared and finally fattened in summer on the best pastures at about $2\frac{1}{2}$ years. With the area of fattening pastures mentioned it would usually be the custom to buy in ten or twelve additional stores in spring, and on most farms of the class under consideration, a "flying flock" of ewes would be kept for fat lamb production, both ewes and lambs being sold off in summer and early autumn. It is probable that some 50 acres of grass would be reserved for hay every year and the whole of the $12\frac{1}{2}$ acres of clover would also be mown.

The average number of animals kept on the farm during summer would be :—

20 Cows, including 5 or 6 to be drafted at end of summer ;	
5 or 6 In-calf heifers ;	
40 Calves ;	
38 Yearlings ;	
32 Home-bred two-year-old cattle	} Fattened on best grass ;
10 Purchased cattle	
150 Ewes and their lambs ;	
5 Horses.	

Without going into details it may be stated that the home-grown hay, straw, roots and corn, with the addition of a little purchased cake for the cows, would maintain the winter stock, but it is certain that on an average there would be no surplus for sale and that no winter fattening could be practised without incurring an excessive expenditure on concentrated feeding stuffs.

In these circumstances the total production of the farm per annum would be approximately as follows :—

32 Fat home-reared bullocks and heifers, say 11 cwt. each	352 cwt.
10 Purchased bullocks fattened on grass—net increase, say $2\frac{1}{2}$ cwt. each	25 „
6 Draft cows, say 11 cwt. each	66 „
190 Lambs, about 100 lb. each	170 „
8 Fat pigs, say 2 cwt. each	16 „
Total live weight	629 „
Wool, say	750 lb.
Butter, say	2,200 „

(N.B.—*The increase in weight of ewes would probably be about balanced by losses during winter and in lambing.*)

Assume now that, as a result of the grave national need, 100 acres of the moderate quality grass land are put under the plough, to be worked ultimately along with the existing arable land on a four-course rotation, and that 10 acres of the lightest fattening pastures are also ploughed. This rich land would not be likely to grow corn satisfactorily when newly broken, and should be cropped mainly with potatoes for the first year or two.

If 10 acres of the fattening pastures have been ploughed the number of stock fattened in summer would be reduced and no store bullocks would be purchased in spring. With this exception, it would be desirable to maintain the usual head of cattle so as to provide for the consumption of straw and the making of dung in the winter. The ewe flock would have to be reduced considerably, say to 50, and the number of horses increased to say 9, to provide for the extra cultivation.

The grazing available would be ample for the reduced number of stock, provided that none of the permanent grass were reserved for hay, that about 20 acres of the clover were grazed, and that about 5 acres of the root break were devoted to the growth of green crops, such as maize, vetches, cabbage, kale, rape, etc., for providing supplementary food in early autumn.

The following summary shows the grazing area under the two conditions. The last column shows the area after the new system has come into full working order. The transition period will be considered later.

<i>Summer Grazing.</i>	<i>Before the Change :</i>		<i>After the Change :</i>	
	<i>50 Acres Arable.</i>		<i>160 Acres Arable.</i>	
Fattening pasture	50	..	40	
Moderate pasture	150	..	100	
Clover	—	..	20	
Permanent meadow aftermath	50	..	—	
Clover aftermath	12½	..	20	
Young seeds in autumn ..	12½	..	40	
Stubbles for ewes	12½	..	40	
Vetches, cabbage, kale, rape, maize, etc.	—	..	5	

The winter feeding would obviously be considerably modified, and the supplies of food under the two sets of conditions must first be summarised :—

	<i>Before the Change :</i>		<i>After the Change :</i>	
	<i>50 Acres Arable.</i>		<i>160 Acres Arable.</i>	
Meadow hay	50 acres—	75 tons.	—	—
Clover hay	12½ „ —	25 „	20 acres—	40 tons.
Straw	25 „ —	32 „	80 „ —	110 „
Total long fodder	132 „	—	150 „	—
Less straw for bedding, thatch- ing, etc.	15 „	—	25 „	—
Long fodder for feeding ..	117 „	—	125 „	—
Oats	25 acres —	150 qr.	40 „	240 qr.
			Less grain sold	60 „
				180 „
Tail wheat and barley	40 acres—	40 „		
Roots	12½ acres—	250 tons.	25 „ —	500 tons.
Small and diseased potatoes ..	10 „ —	15 „		

The hay formerly fed to the cattle would largely be replaced by straw and an increased allowance of roots. In all probability some cattle would be fattened during the winter, but for the sake of clearness it may be assumed that the management in this respect is unchanged. The surplus roots would be eaten on the land by store sheep purchased in autumn, and about 200 would on an average be required. The purchase of cake would have to be increased to finish these unless peas or dredge corn were grown for the purpose, but in any case the expenditure on this item would be comparatively small.

The total saleable production per annum of the farm managed on this system would be about as follows :—

32 Fat home-reared bullocks and heifers, say 11 cwt. each	352 cwt.
6 Draft cows, say 11 cwt. each	66 "
63 Lambs, about 100 lb. each	56 "
200 Purchased lambs fattened on roots, net increase, say	
40 lb. each	71 "
40 Fat pigs, say 2 cwt. each	80 "
<hr/>	
Total live weight	625 "
Wool (from ewes), say	250 lb.
Butter	2,200 "
Wheat and barley, at 4 qr. per acre (marketable) ..	160 qr.
Oats (part of crop)	60 "
Potatoes, at 6 tons per acre net (marketable)	60 tons.

Comparing these figures with the corresponding ones set out on p. 145 it is clear that not only would the farm under the new conditions be of greater value to the nation, but the price realised for the increased produce sold would be ample to cover a considerably increased expenditure on labour. The chief additional expenditure in other directions would be :—

Cake for fattening sheep, say average of $\frac{1}{2}$ lb. a day each for 16 weeks = 5 tons.

Artificial manure for additional roots, 28 acres at average of 30s. an acre = £42.

Seed for 55 acres corn crop, 28 acres clover, and 28 acres roots.

The main difficulty would arise in the first three years, and a considerable modification of the working of the farm would be necessitated if the whole of the additional 110 acres had been ploughed up for 1918. It is, however, unlikely that it would be possible to treble the arable area at once. In many cases an increase of some 40 or 50 acres, including 10 acres for potatoes, would be as much as could be secured in the first year. The accompanying table shows the cropping whereby the new system would be in full working order by 1920. Excluding for the first two years the good land devoted to potatoes, the newly-broken land is each year cropped one-half with corn

1917. 50 Acres Arable.	1918. 96 Acres Arable.	1919. 132 Acres Arable.	1920. 160 Acres Arable.	1921. —
Old Arable—12½ acres roots { 12½ " corn 12½ " clover 12½ " roots 12½ " corn 10 " potatoes 10 " roots and green crop. 9 " oat, pea and vetch mixture. 18 " corn 36 " grass broken up.	12½ acres corn. 12½ " clove. 12½ " corn 12½ " roots 12½ " roots 10 " potatoes 18 " roots and green crop. 9 " oat, pea and vetch mixture. 18 " corn 36 " grass broken up.	12½ acres clover 12½ " corn 12½ " roots 12½ " corn 10 " potatoes 18 " corn 9 " roots and green crop. 9 " vetch mixture 9 " roots and green crop. 18 " vetch mixture 18 " corn 29 " grass, broken up.	12½ acres corn. 12½ " roots. 12½ " corn. 12½ " clover. 10 " corn 18 " clover 18 " corn 18 " corn 18 " corn 18 " corn 9 " roots, potatoes and green crop. 9 " vetch mixture 9 " corn 9 " roots, potatoes and green crop. 10 " vetch mixture	Vetch mixture. Corn. Clover. Roots, potatoes and green crop. Corn. Roots. Corn.

and one-quarter each with roots and vetch mixture respectively. The vetch mixture is intended for mowing as a hay crop, or, if required, for silage or soiling purposes. After it has been cleared the land should be either half fallowed as a preparation for wheat, or sown with rape or white turnips to be folded on the land as a preparation for spring corn. In either case the corn crop would be seeded with rye-grass and clover.

In the third year the potato land takes its place as part of the ordinary arable land.

If it had been possible to break up for 1918 more than the 36 acres of the moderate grass-land, plus 10 acres of the fattening pasture, such excess could be cropped with corn again in 1919, and then be treated as part of the newly-broken land.

It would be easy to improve on the system suggested and to increase the production to a much greater extent, but the simplest possible case has been taken for the sake of clearness.

*This article is also issued as Food Production Leaflet No. 40,
copies of which can be obtained on application.*

SUPPLY OF SILOS BY THE FOOD PRODUCTION DEPARTMENT.

IN view of the shortage of the usual feeding stuffs for cattle, the Food Production Department is satisfied that it is both commercially to the interest of farmers and nationally important that the use of silage, on up-to-date lines, should be greatly extended. The Department is, therefore, prepared to help agriculturists, who wish to build silos on their farms, in the following ways :—

- (a) By giving expert advice in all cases where the construction of a silo is contemplated.
- (b) By supplying free of charge full working drawings, specifications and bills of quantities for two sizes of silos constructed in either reinforced concrete or reinforced brick work, in cases where the landowner or farmer wishes to make his own arrangements for building the silo. (The drawings, etc., can be seen at the office of the County Agricultural Executive Committee, and obtained from the Food Production Department).
- (c) By lending at a moderate charge all forms and centering (moulds) needed for the construction of one of the above standard silos, and facilitating the issue of permits for materials.

- (d) By contracting with the landowner or farmer for the complete construction of silos at a fixed price, which will be quoted after investigation of local conditions.
- (e) By assisting anyone who wishes to construct a concrete or brick silo of some approved type, but of a size or design other than one of the standard types mentioned above, to obtain Priority Certificates for the materials needed. (Special designs cannot be provided by the Department in such cases).

It is to be clearly understood that while the Department

Silo of 100 C Type.

is prepared to do all that it can to help farmers in this matter, nothing stated herein or upon the drawings or other particulars supplied by the Department shall be construed to imply a guarantee of any of the matters or things referred to.

The Silo.—Two sizes of silo have been provided for :—

Size 100	{	15 ft. diameter by 30 ft. high.
		Capacity 5,300 cubic ft. or nearly 200 cubic yards.
		Holding, say about 100 tons of silage. Suitable for a herd of about 25 cows.
Size 50	{	12 ft. diameter by 24 ft. high.
		Capacity 2,710 cubic ft. or about 100 cubic yards.
		Holding say about 50 tons of silage. Suitable for a herd of about 12 cows.

Each size can be constructed either in reinforced brickwork, style "B," or in reinforced concrete, style "C." Thus for reference purposes a silo built in brick 15 ft. diameter by 30 ft. high would be described as a "100 B" silo, and one of 12 ft. diameter by 24 ft. high made of concrete would be styled a "50 C" silo.

Each silo takes the form of a hollow, round tower covered with a wooden roof in which ventilation is provided. It is

fitted with a large door at the top through which it is filled. There are also a number of smaller doors, arranged one above the other up the side of the silo, which are used in succession as the level of the contained silage sinks, for its delivery when required for feeding. Provision is made for suitable drainage and for steps by which the doors can be reached from the ground. These silos are intended to be filled with un-chaffed crops by means of the ordinary elevator with horse gear such as is to be found on many farms. There is nothing, however, in their construction to prevent farmers from adopting the American system of chaffing the crop and blowing it into the silo if they prefer this method of filling, and have, or can obtain, the necessary plant consisting of engine, chaff-cutter and blower. The Department cannot, however, undertake to obtain the necessary permits for either the manufacture in this country, or shipment from abroad, of chaff-cutters and blowers for this purpose.

Silo of 50 B Type.

Cost of the Silo.—In order to obtain an approximate idea of the cost of a particular silo, it may be assumed that in situations where there are no special local difficulties and where good, clean sand and ballast are readily obtainable, a concrete silo of size 100 C will cost at the present time roughly £310, and one of size 50 C roughly £210.

Where bricks are more easily obtained than ballast, "B Type" silos will probably be preferred, costing roughly £340 for size 100 B, and £235 for size 50 B. In each case it is assumed that the purchaser will himself cart the materials to the site. The estimated weights for each type are as follows:—

100 B	100 C	50 B	50 C
140 tons.	102 tons.	95 tons.	70 tons.

Site for the Silo.—To save labour the silos should be built close to the cattle-shed, and, if possible, should deliver straight into them. It is very necessary that there should be a good road and ample space around the base of the silo on the side from which filling operations are to take place.

Crops for the Silo.—The Technical Division of the Department is prepared to give information as to the choice of suitable

silage crops and as to the process generally. The following is a list of crops which could be well and efficiently preserved for cattle-fodder if a silo were erected in time for their reception this year, or may be grown for silage in 1919.

Approximate Acreage required to fill Standard Silos.

<i>Crops for Silage.</i>	<i>Silo "size 100." Acres.</i>		<i>Silo "size 50." Acres.</i>	
Maize	6	..	3	..
Oats and vetches	9½	..	4½	..
Lucerne (2 cuts)	9½	..	4½	..
Red clover and rye-grass	13	..	6½	..
Red clover	15	..	7½	..
Meadow grass	17	..	8½	..
Sainfoin	12	..	6	..

Advantages of Silage.—1. It is a means of preserving green fodder in a succulent state for winter feeding.

2. It is independent of weather, and is, therefore, safer than hay-making in wet seasons.

3. On heavy clay lands or on light soils in dry districts, where roots are precarious, there is almost a certainty of obtaining a silage crop.

4. It is cheaper than root-growing under unfavourable conditions.

5. If the silaged crop is sown in early spring, or, preferably in autumn, it can be got off in time for turnips or rape to be taken, or a bastard fallow made.

6. The usual silage mixture of oats and vetches is a useful cleaning crop. Stubble land, therefore, which in the ordinary course would be bare-fallowed, may safely be sown with oats and vetches and cleaning completed in time for autumn corn by means of a bastard fallow.

7. Stock fed on silage made from leguminous crops, *i.e.*, clover, lucerne, sainfoin and vetches, will require less oil cake than stock fed on roots; moreover, such crops tend to increase the fertility of the land.

8. It will enable poor heavy land now in grass to be brought under tillage, cleaned and improved.

9. The labour involved in feeding silage is very much less than that of feeding roots.

10. It will be seen by a reference to Leaflet No. 9 (to be obtained from the Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1), which deals with *Ensilage*, that in cases where a farmer finds himself short of the usual silage crops the silo may be filled up with coarse grass, hop-bines (directly the hops are picked), and even nettles and weeds. Materials which otherwise stock would reject, may be made into edible silage.

FARM COSTING.

L. F. FOSTER, F.L.A.A., F.C.I.S.

University College of Wales, Aberystwyth.

General.—Systems for ascertaining the cost of production in manufacturing concerns are quite common in Great Britain. They aim at ascertaining costs for one or more of the following reasons :—

For fixing the selling prices of the articles produced.

For supplying figures for future use.

For submitting tenders in competitive trade.

For checking and regulating the various items of cost.

For comparing one year's working with another, and the manufacture of similar articles under the same, or varying or different conditions.

Cost accounts may be grouped as follows :—

Departmental Costs.—These are used for finding the cost of working each department or section of a business.

Multiple Costs.—These are applicable to an undertaking where a variety of products is manufactured bearing little or no apparent relation to one another in cost or in selling price.

Terminal or Contract Costs.—These apply to an undertaking where definite contracts are entered into, in which the costing is definite or terminating.

Single or Output Costs.—These are applicable to undertakings producing the same article all the year round, in which case the unit of cost per quantity produced is the vital factor.

Farm costing has only been experimented with in Great Britain, and has not yet become a general practice. Indeed, it is still in its infancy (even in the case of large farms and country estates) and is likely to remain so until the farming classes become more acquainted with the keeping of financial accounts in the first instance and realise the importance of them and the possibilities of their relation to cost accounts.

Costing systems have become built up in commercial life subsequently to the application of efficient methods of book-keeping in connection with the financial books, and the need for such systems has arisen by reason of the highly industrialised efficiency now common, and the competitive methods as now practised. Until, therefore, the farming classes adopt a good system of financial accounts, and thoroughly understand the working and the importance of them (efficient book-keeping amongst farmers is still uncommon), the importance of cost accounts in farming remains to be realised.

No two businesses which manufacture or produce different articles can adopt the same method of keeping cost accounts ;

for a costing method must be brought down to fit in with the exact requirements of the undertaking. A business cannot be brought into the four corners of a particular costing method for the reason that every business possesses peculiarities of its own which require special consideration in devising a method of costing which will prove efficient. Furthermore, it is correct to state that no two farms can adopt the same method of costing in detail, but the principles of costing will, of course, be the same in every case. The system, so far as costing principles are concerned, always remains the same, but the method by which the principles are carried into effect is exceedingly variable. The method of costing for every farmer desirous of adopting a costing system must be specially prescribed, and every farm must be considered separately, for considerations apply to one which may be entirely absent in another, and may require the costing system to be devised upon certain well-defined lines. General published costing systems, therefore, will require to be modified or varied to suit the particular case which may be under notice. Every individual farm, therefore, should be specially considered in devising a method of farm costing. If developments take place on a farm, the costing system may require to be expanded to suit the new conditions, and the method may require to be altered to some extent. If a market garden were to be cultivated as an adjunct to a farm, it is evident that a separate section of the costing system would be necessary for the garden. It should be stated here that any costing system should be carried out quite apart from the financial system of accounts. Considerations of principle which it is necessary to keep in mind in the financial system may be modified or even disregarded in the costing system, for the two systems are designed to serve widely different purposes. In the financial system, statements of the gross and the net profit over a certain period are aimed at, with the collection of information showing the sources of the profit, together with a statement of the assets and the liabilities as existing on a certain date. In the costing system the aim is to show the profit or loss on each section of the undertaking, after taking into consideration the use of the assets employed therein. As the selling price of farm produce is fairly well fixed, either in the local or in the central market, normally depending upon supply and demand, competitive selling of stock and produce is almost absent. In such cases the costing system should aim at effecting economy in expenditure so as to reduce the cost of production.

The following system, which it is suggested will be found to be comparatively simple in use, as costing systems go, will provide all the information required for the purpose of regulating and organising the working of farms. It can be applied either to large or to small farms, and also either to farms individually or collectively.

Only the most important items of expense are here dealt with, but it is suggested that it includes the nucleus of an efficient costing system, and items and accounts which may be found to require the most attention, and which are no doubt the most important, are briefly explained.

SCHEME FOR THE INSTITUTION OF A COSTING SYSTEM FOR FARMS.

The cost of production and the profit or loss on each section of the farm are what is required. Separate cost sheets, cost cards, or a page of a cost ledger should be provided for each section for which it is desired to ascertain costs. A specimen ruling for such a cost sheet is shown in Appendix I. (p. 163). †

A cost sheet will be required for each field or patch of ground cultivated or grazed, also for the piggeries, poultry, vegetable garden, etc. It will be necessary either to name or number each individual field or patch for purposes of identification. As it will be necessary to charge to some of the cost accounts a proportion of the rent and rates of the farm, each patch or field thus described should have assigned to it a charge, consisting of a sum of money representing rent, rates, and taxes. The sum to be charged to the various fields will need to be calculated equitably in relation to the total of the expenses named. Where a separate rent is paid for a field, such rent would of course be the amount to take into the cost account, the general rent being apportioned over the other parts of the farm. Similarly, where rates or taxes are paid on individual fields, such sums should be taken direct to the cost accounts concerned. In the same way each building which may be in use for a definite purpose should likewise have assigned to it a rental value. Such buildings would include cow-houses, stables, and the farmhouse. A small building for the storage of loose general tools may be omitted from this category, but one used exclusively for the storage of tools of a particular section of the farm should be taken into consideration.

At the end of the year the rental value of the farmhouse would be distributed over the other cost accounts in accordance with the various activities which had been carried on during the year, and also in accordance with a scheme for fairly

distributing the amount. By reason of the fact of its being necessary to take such expenses into account, the cost accounts must be annual accounts, corresponding with the financial year of the farm, especially since the annual valuations will be brought into the costing system as well as into the financial accounts.

Books Necessary.—In all costing systems there are direct and indirect expenses. Direct expenses include all those expenses which can be immediately and wholly charged to the cost account concerned, *e.g.*, seeds for a particular crop. Indirect expenses include general administrative and supervision expenses. The books which it will be necessary to keep are the following :—

(a) *Goods, Stock, and Stores Received Book.*—In this book should be entered the cost price of all goods, live stock, and stores received on the farm, as and when received, irrespective of whether the transaction is a cash transaction or one on credit. If the book is ruled in columnar form it can be totalled periodically, say monthly, and the cost-sheets entered up therefrom in summary form, cross referencing being employed. The items should be debited to the various cost accounts affected, and a Purchase Adjustment Account credited, so as to effect the double entry. The credit entry should be made in total. (See Appendix II., p. 164.)

(b) *Sales, Stock, or Goods Outwards Book.*—In this book should be entered the selling prices of all stock or produce sold, as and when sold, and irrespective of whether the transaction is for cash or on credit. It should follow much the same method of working as the Goods Received Book, but as it will work conversely to that book the entries made therein should be debited in total to a Sales Adjustment Account and credited in detail or in summary form to the various cost accounts affected. A ruling (with variations of heading) similar to the Goods Received Book (see Appendix II., p. 164) will serve for this book.

(c) *Transfer Book or Journal.*—This book should be used for recording transfers, apportionments, and adjustments between two or more accounts in the costing system, *e.g.*, the transfer of manure from the stables or the piggeries to the various fields. No transfer whatsoever should be made except through the medium of this book, as otherwise valuable and mutual dealings between two sections of the farm will be unrecorded in any book of original entry. Moreover, the omission to enter a transfer in the Transfer Journal may be the means of leaving a

transaction unrecorded in the Cost Ledger, and, as any costing system must provide for the taking into account of every detail, such an omission would weaken the system. There will no doubt be such items as rent, rates, taxes, insurance, and other periodical expenses to be met, which would not seem to come within the definition of the Goods Received Book. These may conveniently be passed through the Journal preparatory to their entry into the Cost Ledger. In such cases the entry would be as follows :—

	Dr.	Cr.
Rent	£100 0 0	
To General Adjustment A/c ..		£100 0 0

The ordinary ruling for a Journal will suffice for this book.

(d) *Wages Book*.—Time-sheets for each workman employed on the farm should be kept. These should be written up daily by the workmen or the foreman, and totalled and signed by the foreman at the end of each week. The time-sheets should then be summarised according to the particular work upon which a man has been employed, and entered into the Wages Book. This book should be totalled periodically and the amount thereof debited in summary form to the cost accounts concerned, the total being credited in one sum to a Wages Adjustment Account. The amount deducted for national insurance should be taken into the summary of wages, and the employer's contribution distributed over the sections on which the workman has been engaged, the whole being taken into the Wages Book. When the insurance cards are stamped no further attention need be given in the costing system to the cost of the insurance stamps, these having already been taken into account. The rent of a cottage in which a workman may reside free of rent should be allocated at the end of the year to the accounts of the various sections on which the workman has been employed. Perquisites of office should be dealt with similarly. Such items should be passed through the Journal, debited to the various cost accounts concerned, and credited to the Wages Adjustment Account. (See Appendices III. and IV., pp. 165 and 164 respectively.)

(e) *Cost Ledger*.—This should contain the various cost-sheets and could conveniently be a loose-leaf ledger. The cost-sheets could then be taken out and bound up separately year by year, one year's costing forming a separate volume. (See Appendix I., p. 163, for specimen cost-sheet.)

Special Considerations.—Some of the accounts will require very careful treatment if the result aimed at is to be portrayed

in a form which will leave little or nothing to be desired. It may, therefore, be advantageous to consider some of the most important accounts.

Sheep Account.—This account will contain the following items, amongst others :—

<i>Dr. side.</i>	<i>Cr. side.</i>
Initial cost or valuation.	Proceeds of Sales.
Cost of ram service.	Valuation at end of year.
" special food.	
" grazing (portion of rental of fields).	
Wages.	
Balance (profit) to Costing Profit and Loss Account.	

If other stock in addition to sheep have grazed from the same field, and at the same time, *e.g.*, horses, the rental value of the field should be equitably apportioned between the several classes of stock. If stock have been grazed for a portion only of the year on a particular field, the question of the relative value of the field at the different periods of the year should be taken into account in charging up the rental value. Also, in view of the fact that sheep, cattle, and horses may graze the same field, either together over a definite period, or in varying numbers over that period by reason of sales, purchases, rearing, etc., it is desirable that stock record cards should be kept, giving particulars as to the numbers of the various classes of animals grazed, and the periods of grazing. In addition, daily records of the work which has been done on the farm, especially with regard to the transfer of stock, implements, materials, produce, manure, food, etc., should be kept, preferably by the foreman. Much of the information contained in these records will need to be taken into consideration when writing up the Journal. No more than the actual rental value (rent, rates, and taxes) should be charged over the whole of the various accounts during the course of the year.

Crop Accounts.—These accounts will contain on the Dr. side the rental value of the field, the labour expended upon it, the cost of seeds, manure, and harvesting expenses ; and will be credited with the proceeds of the sale of the produce, together with the valuation at the end of the year. The profit or loss should be transferred to the Costing Profit and Loss Account. Where similar produce is grown on two separate fields, either one account may be opened for the whole crop or as many accounts may be opened as there are distinct fields or patches.

Pigs Account.—This account should be made up as follows :—

<i>Dr. side.</i>	<i>Cr. side.</i>
Initial cost or valuation.	Sales.
Cost of boar service.	Manure transferred to other parts of the farm.
„ special food purchased.	Valuation.
Rent of piggeries (rent of land, plus proportion of initial cost of erection of piggeries).	
Wages.	
Food transferred from other parts of the farm, and grown thereon.	
Profit to Costing Profit and Loss Account.	

It is suggested that the initial cost of the erection of the piggeries should be capitalised in the costing system and a portion written off each year to the Pigs Account until the capital account is entirely extinguished. The capital account should be written off in three or five years, after which period all repairs or additions (excepting substantial additions) should be charged to the Pigs Account as and when incurred. The valuation of the pigs as entered in the Pigs Account should include also the value of the piggeries after the Capital Account has been extinguished.

As regards the food grown on the farm and consumed by the pigs, it will be necessary to assign to this a certain price. It should be the current local market price, this price being that which would have been obtained had the produce been sold on the market, and also the price which would have been paid had it been purchased on the market. It will also be necessary to fix upon a fair and reasonable price for the manure credited to the pigs.

Milking Cows Account.—This account will be debited and credited as follows :—

<i>Dr. side.</i>	<i>Cr. side.</i>
Initial cost or valuation.	Sales of animals.
Rental value of cowhouses.	„ milk.
„ „ grazing meadows.	„ butter.
Cost of purchased food.	„ cheese.
„ bull service.	Transfer of manure to land.
„ conveying milk to market or station.	„ calves to Grazing Cattle Account.
„ food grown on the farm and fed to the cows.	
Wages.	
Depreciation on milk churns and other loose plant.	
Profit to Costing Profit and Loss Account.	

If it is desired to keep a Dairy Account, some of the items included above would need to be taken into that account.

in which case it would be necessary to charge the milk up to the Dairy Account at a fixed price.

The same remarks apply in the case of milking cows as in the case of pigs in regard to the price of the food grown and consumed on the farm. A special account for the valuation or cost of milk cans and other loose plant connected with the cows should be opened, and an amount, representing depreciation, written off annually to the Milking Cows Account ; but only so much of the capital account representing depreciation should be written off as is written off the general valuation of such articles by the valuer at the end of the year.

Where calves are reared apart from the cows, the value of the calves should not be transferred from the Cows Account till they are sold, or finally transferred as grazing cattle to the Grazing Cattle Account, or otherwise disposed of so far as the Cows Account is concerned. The milk which is thus fed to the calves and the labour connected therewith will not need to be otherwise specially accounted for, as the calves will remain for the time being part and parcel of the Cows Account.

Milk records are not dealt with here as they form no part of the cost accounting system ; but they should of course be kept, when the average cost of milk per specified quantity can be obtained, as also can the selling price and other figures connected with the production of milk. Comparative figures year by year, or oftener, will prove most valuable.

Horses and Carts.—It will be a good plan to ascertain or estimate the cost per day of keeping a horse and cart in working order (Sundays excepted) including depreciation, but excluding wages. The average cost over the past year, if available, should be taken to commence with. It will be necessary to check the unit of cost annually or oftener. Sections of the farm which have benefited by horse and cart labour (daily records should be kept) can be charged at frequent intervals on the basis arrived at.

At the end of the year the total cost of keeping the horses and carts in working condition can be accurately obtained, when any balance appearing on the account can be distributed proportionately over the accounts affected. If too much has been charged under this head it will be necessary to credit the accounts concerned, so as to retain no balance on this account. In this case it will be necessary to open separate capital accounts for (i.) horses, and (ii.) carts, waggons, etc., and also a separate working account. The latter will appear as follows :—

Horses and Carts Account.

<i>Dr. side.</i>	<i>Cr. side.</i>
Horse keep.	Transfer to Wheat Crop.
Repairs to harness.	„ Turnip „
„ carts and waggons.	„ Hay „
Shoeing.	„ Beet „
Wages.	„ Rye „
Depreciation of horses, saddlery, carts, and waggons (not exceed- ing the amount written off in the annual valuation).	etc., etc.

If desirable, the cost of horses and implements (harrows, ploughs, etc.) can be treated in this account.

Machinery.—Bone-crushing, chaff-cutting, and other similar machinery may be included in this account, which should include the following :—

<i>Dr. side.</i>	<i>Cr. side.</i>
Initial cost or valuation.	Valuation.
Cost of petrol, or other power used.	Transfer of balance to
„ repairs.	accounts concerned.
Wages.	
Depreciation (not to exceed the amount charged in the valuation).	

In this case also daily records should be kept of the particular work done, and the sections of the farm benefiting thereby.

Garden Tools.—A capital account of these should be kept and the amount representing depreciation written off annually should be debited to the Garden Account, the working of which will follow on the same lines as the other revenue accounts mentioned, and will be comparatively simple in construction.

Repairs to Implements.—If desirable, instead of debiting the various accounts directly with the cost of repairs, the repairs to the various classes of implements may be debited to the capital accounts concerned, and the balance of the accounts, after taking into consideration the depreciation, may be distributed over the accounts which have benefited by the use of the capital assets.

Drainage.—Where a scheme of drainage is carried out which will benefit the particular field drained for several years, the whole expense of carrying out the drainage system should be debited to a special account. The amount standing to the debit of this account should be written off to the particular field drained over a number of years, say five to ten. If the field is used for crops, the various crops accounts will bear the annual charge ; and if used for grazing, the accounts of the various classes of stock grazed will be debited.

Salaries.—Salaries paid to the manager, cost clerk, and farm foreman should be debited to a special account, and the amount standing to the debit thereof should be distributed annually or oftener amongst the various accounts in the cost system. No balance will appear on this account at the end of the year. The basis of apportionment over the various sections of the farm will be a matter for consideration.

Office Rent, and General Administrative Charges.—These charges should be apportioned equitably over the various sections of the farm at the end of the year.

Self-Balancing Ledger.—If on starting the cost system—when the commencing balances are written in—an account corresponding with a capital account as found in the financial books is introduced (which, for this purpose, may be called a Valuation Account or a Valuation Adjustment Account), and if the four books as outlined above have been written up correctly and accounts raised as indicated, the cost ledger will be self-balancing, and will be capable of being proved to have been written up correctly so far as debits and credits are concerned. Before the annual valuations are entered into the various accounts a trial balance should be constructed to ascertain whether or not the ledger does in fact balance. After the valuations are entered up the accounts may be closed.

Closing the Ledger.—The several Adjustment Accounts should be closed and the balances transferred to a Trading or Working Account. Naturally the balances on these accounts will appear (in total) on the opposite side of the ledger to the several balances appearing on the other accounts in the ledger, and the profit or loss as shown by the trading account will likewise appear on the opposite side. This, however, is merely a means of closing the Adjustment Accounts, which are no part of the cost system, but accounts introduced for the purpose of effecting a self-balancing ledger.

The cost accounts may now be balanced and closed to a Costing Profit and Loss Account. In this account the balances will appear on the correct side, and the resulting balance—a profit or a loss—will equal the balance as shown in the Trading Account. This amount should be posted to the Valuation Adjustment Account.

A Balance Sheet or Statement of Balances can now be constructed, so as to complete the whole structure of the cost system, and the result will principally be the following :—

On the Liabilities side will appear the balance of the Valuation Adjustment Account and on the assets side the

APPENDIX I.—**COST SHEET: Grazing Cattle.**

		£1 5 9	
		£1 5s. 9d.	
		Signed.....	Foreman.

various valuations as entered on the credit side of the ledger accounts, and these should be carried into the statement of balances in detail. No further notice need be taken of the balance of the Trading or Working Account, this account being no real part of the cost system and it having already served the purpose for which it was created.

Agreement of Cost Ledger with Financial Ledger.—If the financial books have been kept on adequate and scientific lines the profit as appearing in the Costing Profit and Loss Account should equal the profit as appearing in the financial books. When this proof is established the two systems, which in themselves have no relation one with the other, will be absolute proof of accuracy so far as debits and credits are concerned. It is just possible, however, that certain adjustments may be necessary before the two items of profit will agree. No costing system may be said to be arithmetically correct or efficient until an agreement is effected between the two items named.

DRY ROT FROM THE ARCHITECT'S POINT OF VIEW.

HARRY HUTT, A.R.I.B.A.,

Formerly Lecturer in Architecture, Building Construction, Agricultural Buildings, etc., University College, Reading.

Publications on Dry Rot.—This article does not attempt to deal with the various forms of fungoid growths, commonly called Dry Rot, from the scientific point of view, as these have been adequately dealt with in the issue of this *Journal* for August, 1916, by Dr. P. Groom, and also in Leaflet No. 113 on Dry Rot published by the Board in 1917. Both publications also deal generally with practical points important not only to architects and builders, but also to estate owners, agriculturists and others who may have to erect buildings for various needs.

It may be premised that the average architect possesses sufficient theoretical and practical knowledge of this dread scourge to enable him to avoid methods of construction likely to induce the disease.*

Supervision of Work.—Unfortunately, however, most architects, especially those in the provinces, in most instances through considerations of cost, are not able to employ an efficient clerk of works on the majority of their works to see that all details set out in specification are carried out. The architect himself can only make periodical visits, and there is therefore opportunity for carelessness or neglect, and the contractor himself is in the same position as the architect with regard to personal supervision. Much small detail of the work, therefore, must be executed without direct supervision of the principals intimately concerned, and such supervision consequently falls on the foreman who, probably through ignorance, does not realise the importance of the details in specification directly relating to this particular disease, and unfortunately the majority of the ordinary building artisans are in a similar position. The poor architect, if anything does go wrong,

* Most architects are no doubt familiar with the more general publications dealing with Dry Rot, and in preparing these notes the writer has carefully considered the various points raised by their authors. In particular, the following publications may be mentioned:—

H. Marshall Ward, M.A., F.R.S., F.L.S., *Timber and Some of its Diseases*.

W. H. Bidlake, M.A., A.R.I.B.A., *Dry Rot in Timber*, 1889.

Paul Ogden, F.R.I.B.A., "Report on Dry Rot," *Journal of the Royal Institute of British Architects*, 6th June, 1908.

F. Barnes-Hewitt, F.S.I., "Dry Rot," *Carpenter and Builder*, 20th June, 1908.

Wm. Woodward, F.R.I.B.A., F.S.I., "Dry Rot in Buildings," *Journal of the Royal Institute of British Architects*, 8th January, 1910.

has to pay the penalty, not so much for his own sins of omission and commission as for the acts of those who may have erred through ignorance or carelessness.

Importance of Supervision.—In making investigations extending over a long period in connection with dry rot the writer's experience has been that, in the majority of cases inspected, the work had been carried out without the advice or supervision of an architect. In other instances, more especially those where English timber was concerned, it was noticed that freshly-cut unseasoned material, converted on the estate, had been used principally in repairs to cottages, farm buildings, etc., and the inevitable result was a fine crop of dry rot.

Instruction for Employees, etc.—In order to eradicate this pest it seems essential that all workmen, whether in the building trade or employed as estate workmen, should receive special instruction on dry rot and the preventive measures necessary to obviate as far as possible its occurrence. This instruction should not be confined to carpenters and the like, but be given to all engaged in the building trade, for reasons that must be obvious to anyone with even slight knowledge of building operations. This may possibly be achieved in two ways :—

(a) By wide distribution, amongst those already directly engaged in building work, of literature dealing with the subject from a practical point of view. This distribution might be arranged with the co-operation of various bodies interested, such as the Board of Agriculture, the Royal Institute of British Architects, the City and Guilds of London Institute, the Worshipful Companies of Carpenters and Joiners, Bricklayers, etc., etc., the Surveyors Institute, etc.

(b) By giving future artisans, etc., instruction on the subject at all technical institutions.

This subject should, in the writer's opinion, be included in the Board of Education's syllabus for the lower examination in building construction, as many artisan students unfortunately do not remain in the schools to prepare for the higher examination, and therefore miss this subject. It would be of great benefit to the country at large and to the building trades in particular if all employees under 18 years of age were compelled to attend technical classes in their working time for a certain number of hours per week. A lad who has had a hard day of manual labour cannot be expected to do his best work at evening classes. The same remark applies equally to evening lecturers, who in many instances have already done more than an eight-hour day before the evening session commences.

It is proposed in this article to set out briefly some of the conditions conducive to the production of dry rot and also to give practical instructions to the worker as to the precautions that should be taken to prevent, as far as possible, its germination and growth.

Conditions Suitable for Producing Germination and Growth of Dry Rot.

—It may be taken as an axiom that where dry rot appears its generation is not spontaneous, but the germs of the disease must have been present in some form or other either in the timber or in the surroundings. The development of the dry rot merely indicates that local conditions have either stimulated the germination of the spores of the fungus, or have caused portions of mycelium already present to grow out and cause fresh injury. It is therefore essential that the following conditions should be either avoided or overcome in any building :—

- (a) Damp sub-soil causing damp foundations, etc.
- (b) Vegetable matter, roots, cuttings of trees, shavings and waste pieces of timber buried in sub-soil or left under floors.
- (c) "Making-up" under ground floors with ordinary excavated material, which may contain germs of disease. instead of using hard impervious dry core.
- (d) Improper stacking of timber both in stock-yard and on site of building, especially if timber is of English growth.
- (e) Use of timber stacks and interior of new buildings by insanitary workmen as "conveniences."
- (f) Warm, moist, stagnant atmosphere likely to be found under floors and in cellars where ventilation is imperfect.
- (g) Use of unseasoned or immature timber.
- (h) Use of infected timber. Timber may become infected on board ship and in the merchant's and builder's yard, or may have been converted from trees attacked by fungus growths in the forest.
- (i) Direct communication between timber and walls recently built which necessarily contain moisture.
- (j) Use of impervious floor coverings such as oilcloth, cork carpet, etc., which cause condensation and prevent free circulation of air.
- (k) Painting, etc., on unseasoned timber so that moisture is confined in the wood.
- (l) Stoves, ranges and hot-water pipes under floors where surrounding air-spaces are not efficiently ventilated.
- (m) Imperfect removal of infected timber, etc., the spores and mycelium remaining, even though in brickwork or concrete, producing a recurrence of the disease.

(n) Carriage of spores, etc., from infected material to timber stacks, and also to freshly-worked material by carting infected material to builder's yard or by non-cleansing of tools used in removing infected timbers, etc.

Measures of Control.—Preventive.—The following instructions if carefully carried out would to a large extent prevent the germination and growth of dry rot, and should be carefully studied not only by architects but also by timber merchants, contractors, estate owners, farmers, and all workmen who may be concerned in building operations.

1. Make careful inspections of all fresh cargoes of timber as soon as unloaded.
2. Make careful periodical inspections of all timber in stock-yards and test by gimlet, auger, appearance and odour whether indications of disease are present.
3. It is a common practice to convert trees having rotten butts after cross-cutting the diseased portion. If timber from such trees be carefully examined, distinct traces of *hyphæ* may be found, in some instances extending almost to the tip of the tree. The writer has condemned quantities of converted English timber felled during War-time for this very reason. Any tree found with rotten butts should be utilised for firewood only. Carefully examine all timber for traces of red stripe and discard any showing signs of same.
4. Remove all vegetable matter from site and do not use any excavated material likely to contain vegetable matter for "filling" under solid floors. "Filling" or "making-up" should be of clean ballast or some such non-porous material, and broken brick, chalk or porous stone only used where non-porous material is not available.
5. Materials suitable for foundations are dealt with in Leaflet No. 113 issued by the Board of Agriculture and Fisheries.
6. Always construct the sleeper wall adjoining main wall as an independent wall, as in illustration "A." This prevents contact of plate with main wall, and ends of joists and boarding should have a clearance as shown. On no account build in ends of timbers on ground floor, but always support on sleeper wall.
7. For cheap work 9-in. brick in cement piers may be constructed at 5-ft. centres, and bearers carried on same to support 3-in. by 2-in. to 4-in. by 2-in. joists, as in illustration "B."

8. Do not fix any timbers in building until absolutely essential, so as to allow walls, etc., the maximum amount of time possible for drying out. Use well-seasoned, dry timber and keep same dry.
9. Do not allow any timber to be in contact with walling or mortar wherever a clearance can be given, as illustration "C." Where it is essential to bed ends of timbers in wall, treat ends with carbolineum or other preservative, and form pocket whole length of wall with damp-course, as illustration "D," and fill in between timbers as they are inserted and pin up in cement.
10. Avoid dampness in walls and damp and stagnant air under ground floor by :—

- (a) Inserting impervious damp course of good quality throughout entire thickness of all walls at least 6 in. above ground line.

N.B.—Tarred brown paper is worse than useless as a damp course. Instruct occupier of house that in making up garden, etc., no earth should on any account be above damp course level.

- (b) Where soil is naturally damp, cover whole surface of site with 4-in. layer of cement concrete after removing top soil. This bed of concrete should have upper part composed of fine stuff and finished off with hand float. Surface concrete made with a large aggregate and left with rough surface must be avoided.

Provide ample ventilation as hereafter described, otherwise surface concrete may cause condensation on under side of floor and so tend to start fungoid growth.

See that all guide-pegs are withdrawn from concrete and holes filled up. Pegs *must not* be left in permanently.

- (c) Where any floor is below ground level arrange for dry area all round or insert vertical damp course, as shown in illustration "E," and use solid floors.
- (d) Provide ample ventilation under all floors by means of air bricks in external walls, not less than 9 in. by 6 in., as shown in illustrations "A" and "B."

Leave ample openings in all internal walls and build all sleeper walls honeycomb to ensure thorough circulation of air. Use simple-pattern air bricks with maximum-size apertures possible.

Where party walls or solid floors intervene obtain through current of air by laying 6-in. socketted drains as connecting flues.

See that all air bricks are clear of obstructions and do not block them internally by placing end joists close against wall, where height of floor above ground necessitates joist being at level of air brick, but allow clearance as in illustration "F."

Instruct occupier of house that air bricks under floors do not cause draughts in rooms above and therefore must on no account be blocked up.

It is essential that there should be no stagnant air under floors, and efficiency of ventilation may be considerably

ILLUSTRATION "A"

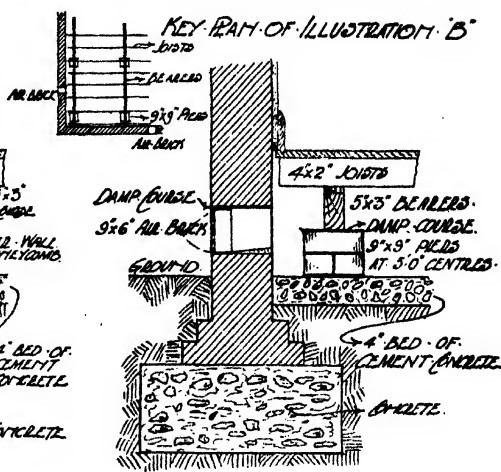

ILLUSTRATION "B"

ILLUSTRATION "C"

ILLUSTRATION "D"

ILLUSTRATION "E"

ILLUSTRATION "F"

increased by building air flues in chimney-stack separated from smoke flue by stout tile or iron wyth, or by carrying up in walls Haden's or other approved ventilating flues or butt jointed pipes as extract flues, as in illustration "G" These flues must be placed in such positions as will ensure through circulation, and should be finished at roof level with 9-in. by 6-in. gratings in open air and not in roof.

The writer has in many cases inserted simple 4-in. galvanised pipes in existing buildings as extracts, which have proved very efficient in increasing circulation and curing dampness.

11. Where surface concrete is compulsory under local by-laws it is cheaper and better to lay boarding in an approved mastic and nail directly into coke breeze, as in illustration "H," than to bed fillets in concrete or to use small joists.
12. Remove all shavings, chips, etc., from under floors whilst boarding is laid where joists are used.
13. Where hot-water pipes of any description are laid under boarded floors :—
 - (a) Form proper brick channels and pack pipes with silicate cotton or other approved insulating material and cover in channels ; or
 - (b) Coat pipes with an approved non-conducting covering and provide extra ventilation in external walls and hit-and-miss gratings over pipes in floor boarding or skirting.

If gratings are inserted in skirting proper flues must be formed to them.
14. Avoid use of linoleum, cork carpet, or similar impervious floor-coverings on ground-floor boarded rooms.

If these coverings are insisted on by occupier a clear border of a minimum width of 6 in. must be left all round room.
15. For preserving ends of timbers, etc., avoid paint and tar which are impervious and not only prevent ingress of damp but also prevent egress of moisture latent in wood which thus confined is likely to cause decay. Use carbo-lineum, etc., as described under No. 9.
16. Avoid paint or similar impervious priming on backs of panelling, dadoes, skirtings, etc., for same reason, and coat with carbolineum or similar preservative. Bore holes at top and bottom of dadoes, etc., for ventilating space at rear.
17. Carry first coat of plaster behind panellings, dadoes, skirtings, etc., but if patent impervious plaster is being used above dado, etc., the coating behind should be ordinary lime plaster. The latter material is porous and will therefore absorb moisture and prevent excessive condensation.

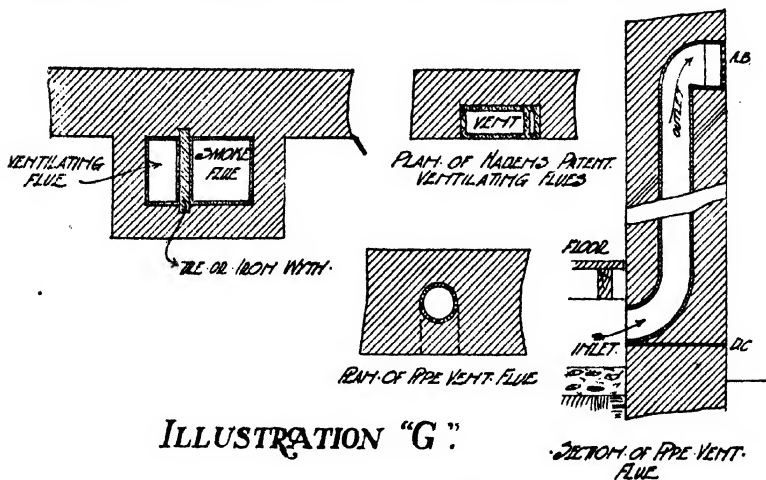

ILLUSTRATION "G"

ILLUSTRATION "I"

ILLUSTRATION "H"

ILLUSTRATION "K"

18. For the same reasons ordinary lime plaster is preferable for use on wood partitions and ceilings supported by timber construction, especially if spaces between timbers are not ventilated.

19. Use breeze or similar patent fixing bricks for securing all grounds and joinery, and avoid wood bricks and pads.

20. On upper floors or flat roofs the following precautions should be taken :—

- (a) Ventilate by 9-in. by 3-in. airbricks having cranked flues rendered to fall to throw rain, etc., outwards, as in illustration "I." Bore occasional holes in joists to provide for through circulation of air and leave suitable openings in internal walls for same purpose.

If latter is impossible, form suitable vertical extract flues, as described under 10 (d).

- (b) Where joists are not bedded in walls leave clearance at ends.

- (c) Always treat ends of timbers bedded in walls, especially those occurring in hollow walls, with preservative, as described under 9.

21. Where pugged floors are constructed the following precautions should be taken :—

- (a) Avoid lime or moist pugging of any description and use either fibrous plaster slabs, silicate cotton, or other approved non-conductor or sound.

- (b) Provide ventilation both *under and over* pugging with air bricks, flues, etc., as described under 20 (a), and as in illustration "K."

- (c) As floor boards on upper floors in all but cheap properties are usually close jointed in some form or other, ventilation through joints must be considered impossible.

22. Special supervision must be exercised by the foreman in relation to sanitation. A notice should be posted on all buildings in course of erection stating that any workman found using wood stacks or interior of building as a "convenience" will be instantly dismissed.

23. Any workman engaged in removal of material infected with dry rot must carefully cleanse all tools used in the work in a suitable disinfectant before leaving the premises.

All infected material removed must be burnt on the site and not taken off the premises.

Aprons, etc. should also be soaked in disinfectant and rough dried before being taken away.

Remedial Measures.—These are fully dealt with in the Board's Leaflet No. 113.

English Timber.—Owing to the War, English timber of various kinds has been used in large quantities, not only for war purposes but also for ordinary building work throughout the

country. The writer has inspected large quantities of this material and is of the opinion that a few notes may be of use to estate owners and agriculturists generally, and possibly to those more intimately concerned with building operations. In speaking of English timber reference is intended to soft woods such as Scotch fir, silver fir, spruce, larch, Corsican pine, etc. Much of the timber already converted has been cut out of

FIG. 3.

season ; it is therefore full of moisture and, owing to urgency of demands, has to be used in that condition. It is improbable that imported timber sufficient to supply all requirements will be available immediately at the close of war, but there may be large stocks of English material in hand unless war demands have exhausted the supply. It is most likely that many persons ignorant both of the necessity for proper seasoning and the danger of dry rot may see no harm in using such timber for ordinary building operations. There is in many districts English timber of excellent quality which if properly treated would be suitable for really good-class work. From observations

made in various parts of the country the writer came to the conclusion that two errors seemed fairly general, viz. :—

- (1) Timber converted without any consideration as to sizes likely to be of use to the building trade ;
- (2) Timber stacked in most cases in the open and in the same manner as imported timber.

These points have been remedied in some instances, but if English timber is to be of permanent use it is essential that the needs of the purchaser are considered not only as to sizes but also as to quality, which is directly affected by methods of stacking. All English timbers should be seasoned by " open " piling or stacking, and a diagram (Fig. 3) illustrating this method was issued by the Board through the Home Grown Timber Committee, and copies should be obtained by all estate owners who are cutting and converting timber on their estates.

If English timber is improperly stacked, especially when cut out of season, discoloration and signs of fungoid growth appear very quickly and whole stacks of material may soon be infected. If, however, care is exercised in piling, the material is stored in open sheds, and all trees showing signs of incipient decay in the butt are discarded, good quality timber should be obtainable subject to the proviso before mentioned. The writer has seen roof principals, floor joists, etc., of local-grown Scotch and silver fir as clean and bright as they were when put in over 20 years ago, and there should be no reason why similar good material cannot still be produced.

THE SHORTAGE OF CLOVER SEED IN ESSEX IN 1917.

R. ROBSON, M.Sc.

East Anglian Institute of Agriculture, Chelmsford.

IN August, 1917, the poor crops of clover seed in Essex roused suspicion in the minds of growers that the dearth of bees might be the cause of the seed shortage ; and in answer to an inquiry the following notes on the subject were written :—

The failure of clover plants to produce seed is to be considered from at least two points of view, viz.,

1. The pollination of the flowers by insects, and
2. The destruction of the seed by insects.

I. Pollination of the Flowers.—The pollination is mainly effected by insects belonging to the bee family, of which humble

bees and honey bees are the most important as pollen carriers. The Isle of Wight disease has caused the death of most of the honey bees in Essex, and the writer has heard a bee expert say that humble bees and wasps are also susceptible to the disease, and that the former at any rate have been decreased in numbers as a result. The writer has not himself noticed any diminution in the number of humble bees.

Darwin's experiments on clovers may be summarised as follows :—

Plant.	Seed Production of Plants Covered with Muslin to Prevent Access of Insects.	Seed Production of an Equal Number of Flowers Unprotected.
Red Clover (<i>Trifolium pratense</i>) ..	68	2,720
White or Dutch Clover (<i>Trifolium repens</i>) ..	As 1	is to 10
White or Dutch Clover (2nd experiment) ..	0	2,290
Crimson Clover (<i>Trifolium incarnatum</i>) ..	63	349

The insects which visit clover flowers for the purpose of sucking honey or collecting pollen are given as follows by Müller :—

Clover.	The Bee Family.			Flies.	Moths and Butterflies
	Honey Bees.	Humble Bees.	Other Bees.		
White Clover (<i>Trifolium repens</i>) ..	Very abundant	1 kind	4 kinds	3 kinds	1 kind
Red Clover (<i>T. pratense</i>) ..	some	14 kinds	14 kinds	3 kinds	8 kinds
Hare's-foot trefoil (<i>T. arvense</i>) ..	present	2 kinds	9 kinds	..	1 kind

With regard to *Trifolium repens* there is a general consensus of opinion that the honey bee is the most important pollen carrier.

In the case of *Trifolium pratense* Darwin remarks, "it is at least certain that humble bees are the chief fertilisers of the common red clover." In this flower the honey lies at the base of the tube 9 to 10 millimetres long and the mouth tube of the honey bee is only 6 millimetres long, too short, therefore, to reach the honey. It is recorded that in the United States

and in New Zealand honey bees do not visit red clover ; Müller remarks that in Germany "the honey bee usually visits the red clover only for its honey which its proboscis is not able to reach in the legitimate manner—yet I have now and then seen hundreds of honey bees on a patch of red clover, all busy collecting pollen." Darwin's experience is different from the above, and apiarians generally consider that the red clover is of no use to their bees. Sladen writes : " In consequence of the absence of *humble* bees in New Zealand it was found that the red clover did not produce seed freely. So in November and December, 1884, a number of queens were sent from England to that country, with the result that two species have become established there, and the red clover now yields a plentiful crop of seed."

From the above data it is clear that any shortage of seed in the case of *Trifolium repens* may be due to the death of the honey bees, but in the case of *Trifolium pratense*, the presence or absence of the honey bees would make no appreciable difference. If, however, the humble bees were less plentiful than hitherto, the pollination of the clover in question could not be properly effected, and a small yield of seed would be the result.

2. Destruction of the Seed by Insects.—Considering the matter from the second point of view we know that in 1917, beans, peas and clover were much eaten by *Sitones* beetles, which notch the leaves of these plants every year. They are not, however, responsible for any direct loss of seed as they feed on the leaves of the plants. Last year they were the companions of a very destructive weevil (*Apion apricans*, Herbst.); whilst the *Sitones* beetle was eating the leaves of the clover the weevil named was laying its eggs in the flowers. When the first crop of clover was cut and stacked it was discovered after some days that millions of insects (weevils) were issuing from the majority of the stacks, and were eating the clover in the vicinity. The young clover around the stacks had the appearance of being burnt, and each day the " ring " round the stack increased in area. The weevils got into the stacks in the following way. Whilst the clover was in flower in May and June the weevils laid their eggs in the flowers. When the clover was cut the young weevils resulting from the eggs were in the maggot stage, but the cutting and stacking of the clover did not prevent them from completing their metamorphosis. Every maggot, therefore, which went into the stack gave rise in a few days to a weevil.

When the young weevils issued from the stacks in immense numbers, they ate up the first clover plants in their way, and then passed on into the field to lay eggs for the next generation. Every head of clover in which eggs were laid would produce few or no seeds. The number of weevils was very large, and the damage they would do would be correspondingly great ; in fact, many farmers fed off the second crop or cut it for hay as the promise of seed therefrom was small.

Though the weevils have wings they prefer to *walk* from the stack, and sticky cloths caught large numbers on their outward journey. In the case of one stack, bands of cloth were stretched round like a little fence, half of the length being coated with "Tanglefoot," and half with coal tar and pitch. The latter mixture seemed to be the more effective, as the heat caused the "tanglefoot" to melt and run down to the ground. The experiment sufficed to show that a trench with water and tar would catch the majority of the weevils. The water would prevent the tar soaking into the dry soil and becoming ineffective.

Curtis records several cases of loss of seeds due to this weevil :—

(a) In 1798 $4\frac{1}{2}$ acres produced $16\frac{1}{2}$ bush. of seed ; in 1800 the same ground $7\frac{1}{2}$ bush., the pest being the clover weevil in question.

(b) Another grower stated : "I reckon my loss in the seed crop in 1841, by the clover weevil, at one-tenth." The agriculturists complained later that the yield of seed was far from abundant.

In conclusion, when the dearth of honey bees is considered along with extraordinary numbers of clover weevils in 1917 there is little doubt that the shortage of seed was due to the depredations of the latter ; and it behoves farmers to adopt measures to prevent the egress of the second generation of weevils from their stacks of first-cut clover. Nevertheless, the importance of honey bees and of humble bees must not be overlooked, for there is little or no seed formation without them.

THE following notes on an experiment on the cost of feeding a herd of 11 sows and their produce for the 6 months, October, 1917, to April, 1918, under war conditions, have been received by the Board from a Suffolk farmer, and are published as an interesting historical record* :—

* The result is perhaps more encouraging than the experimenter implies, as he would appear to have obtained good profit through the prices charged for some crops grown by himself. The potatoes, however, were purchased. The cost of production may possibly be higher next winter.—Ed.

" Most of the sows are pure Large White sows, and the boar is one-fourth Berkshire and three-fourths Large White.

" Most of the profit shown (£141 8s. 3½d.) is accounted for by the valuation of October being on the basis of 25s. per score and that of April 28s. per score.

" Also the pigs were carefully bred and exceptionally well-managed by the farm bailiff, and all of them were thrifty and free from disease or accident for the whole period.

" The average loss through death and disease would probably do away with the rest of the profit, so I come to the conclusion that, where the management is good and the stock of pigs is carefully selected and crossed, the price of 28s. per score will just pay expenses, but offers little inducement to farmers who are not experienced in the management of pigs to start pig-keeping. From a food production point of view, however, the figures show very good results for war-time.

" In order to produce 1 lb. of pork, 3 lb. of concentrated food and 20 lb. of vegetable food were consumed, and none of the concentrated food was suitable for human use.

" In a former experiment on the same lines (made before the War) when the pigs were fed entirely on meal, 1 lb. of pork was made by the consumption of 5 lb. of meal.

" To show the ratio of pork produced to food consumed it was necessary to make the valuations on a dead-weight basis, and these valuations were made by one of the best judges in the Eastern Counties.

" In estimating the dead weight of heavy sows, an allowance was made for the unborn pigs. I believe that a much nearer estimate of the dead weight of pigs can be made by the careful valuation of a good judge than by weighing alive and then calculating the dead weight, because the proportion of dead to live weight varies so much in different stages of maturity that live weights are very unreliable, except for mature pigs. I also think that most experiments on pigs are very misleading, because the pigs are shut up in confined places and weighed so often that they do not thrive in the same way that they would do under natural conditions, and if the 'nerves' of pigs are upset, they will not pay for the food.

" Nearly all the pigs sold went to a bacon factory in the Midlands, which reported that the pork was of first-class quality. They weighed from 150 lb. to 220 lb. each. The following figures are of interest :—

<i>Concentrated Food Used.</i>			<i>Price per cwt.</i>			<i>Value.</i>		
	<i>Tons</i>	<i>cwt. lb.</i>				<i>£</i>	<i>s.</i>	<i>d.</i>
Barley meal	2	19	70	18s.		53	13	3
Bran	1	8	84	15s.		21	11	3
Pollard	2	8	42	16s.		38	14	0
Wheat germ	0	15	0	20s.		15	0	0
Bates cake meal ..	0	11	0	24s.		13	4	0
Soya bean meal ..	0	16	56	24s.		19	16	0
Coco-nut cake ..	3	10	0	20s.		70	0	0
Palm kernel cake ..	1	12	28	16s. 6d.		26	12	1½
Fish meal	1	14	14	23s.		39	4	10½
Tail red clover seed ..	1	17	0	19s.		35	3	0
	17	12	70			£332	18	6

<i>Vegetable Foods.</i>				<i>Price per ton.</i>			<i>Value.</i>		
	<i>Tons</i>	<i>cwt.</i>	<i>lb.</i>	<i>£</i>	<i>s.</i>	<i>d.</i>	<i>£</i>	<i>s.</i>	<i>d.</i>
Acorns	5	13	0	6	15	0	38	2	9
Savoy	2	5	0	3	0	0	6	15	0
Carrots	0	17	0	2	10	0	2	2	6
Kohl Rabi	65	3	0	2	0	0	130	6	0
Potatoes	25	15	0	3	5	0	83	13	9
Mangolds	19	10	0	1	10	0	29	5	0
							<hr/> £290	5	0

<i>Result.</i>			<i>Stone lb.</i>		
Weight of pigs sold October to April			788	11	
Weight of stock pigs 3rd April			656	0	
			1,444	11	
Weight of stock 10th October			513	11	
Weight of pork produced 10th October to 3rd April			931	0	

That is, 931 stones of pork dead weight (14 lb. stone) were produced for the consumption of 17 tons 12 cwt. 70 lb. of concentrated foods and 119 tons 3 cwt. of vegetable foods.

That is, 3·035 lb. of concentrated food and 20·476 lb. of vegetable foods produced 1 lb. of pork.

Profit and Loss Accounts.

<i>Dr.</i>	<i>£</i>	<i>s.</i>	<i>d.</i>		<i>Cr.</i>	<i>£</i>	<i>s.</i>	<i>d.</i>
Valuation 10th October ..	481	10	0	Pigs sold October to ..

	£1,361	1	9½			£1,361	1	9½

Profit accounted for by the valuation of October being made at 25s. per score, and that of April at 28s. per score, and also by there being no loss by death or disease.

“The pigs on this farm were better managed and were more thrifty than those on any of my other farms. The cost of litter and labour on carting it was off-set against the value of the manure.”

THE poultry-keeper, in common with all owners of stock, is faced with great difficulties in securing suitable feeding materials for his stock.

**The Feeding of
Poultry.**

The conditions which have produced these difficulties are described and advice as to how they should be met, are given in the following reply by the Rt. Hon. R. E. Prothero, M.P., President of the Board of Agriculture and Fisheries, to a Petition on behalf of poultry-keepers presented by Mr. E. Jardine, M.P. :—

“ At the beginning of the year a careful estimate was made of the amount of concentrated food for live stock of all kinds that we have or shall have in the country between now and the next harvest. This stock-taking includes the oil cakes existing and likely to be made within the period, the oats, tail corn and damaged grain in farmers' hands, the millers' offals that we may expect, the imported grain materials that will have to be rejected as unfit for human consumption—in fact all the larger items of food for live stock which can be brought under Government control. The account revealed an alarming deficiency, and the Board of Agriculture, with the Ministry of Food, had to consider what classes of animals should be served first. It was found that after the working horses on the farms, in the pits, and in the towns had been provided with a bare ration, and when the milch cows had been given sufficient to carry them on until they could maintain themselves upon the grass, there was but a small margin left. That margin has been divided between pigs and poultry. Nothing at all has been allotted to fattening cattle or sheep.

“ That is the situation. There is not enough food to carry on the business of poultry-keepers or any other class of live stock keepers in the ordinary way. Nothing that the Board of Agriculture can do will remove the shortage or create food where it does not exist. The reason that even the allocation of 1 oz. a day per hen bird, together with a reservation of food for utility birds, has been allowed to poultry, is that poultry can to a large extent be fed upon waste materials from the household and the farm by people who are suitably circumstanced, if they are provided with just that minimum of concentrated food which they need to carry poultry through the critical period when they are chicks, and to supplement the food at other periods.

“ *If poultry-keepers will lay themselves out to produce eggs under these conditions, and exercise their ingenuity to make use of every sort of food they can get at, except those I have mentioned*

above, the Board of Agriculture wish to see every possible fowl kept; but they are unable to accept the suggestion contained in the Petition, that poultry-keepers should be supplied with food in the usual way, for the simple reason that it is not there to give them. When your Petitioners state that 4 lb. weight of poultry flesh can be produced in 16 weeks they omit to set down the other side of the sum, namely, the quantity of grain which is consumed in producing this poultry flesh. In so far as the poultry-keepers of the country can make this flesh out of waste, together with the damaged grain, screenings and the like, which has been promised to them, no one is more anxious than myself for their success, but I cannot encourage them for a moment to suppose that they can be allowed sound grain or any of the other materials utilisable for human food, or even that they can be permitted to trench upon the stock that is required for the working horses and the milch cows."

The Present Position.—The position with regard to the use of the ordinary feeding stuffs for poultry may be briefly summarised as follows :—

Wheat, barley, rye, rice and dredge corn may not be used unless declared unfit for human food.

Maize may be used if obtainable, but supplies are extremely scarce.

Butter beans, haricot beans, blue and green peas, lentils and yellow split peas may not be used. Other kinds of beans, peas or pulse may be used.

Oats are not at present prohibited, but supplies are so short that it is in the national interest that they be used with the greatest economy.

Tailings and screenings from all kinds of grain may be used.

Oil cakes, milling offals and other meals (except oatmeal), and *proprietary poultry mixtures* prepared in accordance with the provisions of the Horse and Poultry Mixtures Order (1917) may be used.

The Scheme for Rationing Poultry.—Practically all the food-stuffs in the foregoing classes are placed at the disposal of the Central Rationing Committee of the Ministry of Food, who have appointed Provincial Feeding Stuffs Committees to apportion them to the different classes of stock in definitely fixed quantities.

An Order will shortly be issued by the Ministry of Food under which poultry-keepers may obtain priority certificates entitling them to purchase from their usual corn dealers 1 oz. of oats per hen (hatched since 1st January, 1916) per day, or an equivalent value in other foodstuffs. *Supplies cannot, however, be guaranteed, but poultry-keepers will be in the same position as owners of milch cows and pigs.*

Poultry-keepers may supplement this ration from any stocks they happen to hold, and by the purchase of parcels of suitable foodstuffs the supplies of which are so small that they are not caught up in the schemes for the control of the main animal feeding stuffs.

In addition, a scheme is under consideration by the Ministry of Food and the Board of Agriculture for the distribution of 50,000 tons of foodstuffs for the preservation of the best utility strains of poultry from which the country can be re-stocked. It is hoped that details of this scheme will shortly be published in the Press.

Grain Feeding.—Owing to the demands of human beings for bread it has been increasingly difficult during the War to provide a suitable and sufficient hard corn ration for poultry. Before the War, 2 oz. of grain per head per day was the generally accepted ration for adult poultry.

The scarcity and high price of grain have compelled many poultry-keepers to reduce this ration considerably.

One skilled poultryman obtained excellent results from a ration of $\frac{1}{2}$ oz. of grain per head per day supplemented by an increased amount of mash composed of meals and a large proportion of boiled vegetables and roots.

Other instances have been brought to notice in which fowls have been fed entirely on soft food.

Poultrymen will, no doubt, do their best to obtain their 1 oz. per hen per day ration in the form of some kind of grain, but they must face the fact that this will not always be possible. They should, therefore, use any grain they obtain, or which they have in hand, most sparingly, in order to provide for periods when no grain may be obtainable.

Mash-Feeding.—Fortunately the foodstuffs available for mash-feeding are more plentiful and are not so keenly competed for by other classes of stock. The "ration" may be supplemented from the following foodstuffs :—

Fish-meal.—This is still procurable in fair quantities. Recently a fish-meal has been placed on the market containing such a high percentage of salt that it caused the death of many fowls to which it was fed. A guarantee should, therefore, be obtained from manufacturers or vendors that the fish-meal they sell contains less than 5 per cent. of salt.

Blood-meal, Meat-meal, Bone-meal.—These are still available from the usual sources, and, in addition, many local authorities are manufacturing or preparing to manufacture these meals

from the edible refuse which they collect from abattoirs, hotels, infirmaries, houses, etc. *Waste vegetable matter* is also being dried and pulverised. These foods will be sent out in dry condition, and should be extremely useful to poultry-keepers.

Blood (boiled) and scraps from butchers, and horseflesh where obtainable, are also most useful. Where arrangements are not made by local authorities for the collection and treatment of household waste, poultry-keepers might well combine to organise house-to-house collection by means of boy scouts and school children, at frequent intervals, in order that the waste may be received and used in as fresh a condition as possible.

Fodder Meals.—Some of the ordinary farm fodders when ground give very useful meals. The best known is clover-meal, which is highly valued and extensively used by poultry-keepers. Lucerne (alfalfa) and sainfoin are similar in character and give equally useful meals. The clover leaves obtained as a waste in the threshing of clover seed are very useful where they can be collected. The seed heads of the leguminous plants mentioned make good food either fresh or dried, as do the ripe seed heads of many of the grasses.

Surplus Garden Produce.—All kinds of greenstuffs and roots can be utilised to a certain extent. In the case of roots (small potatoes, turnips, mangolds and carrots) these should preferably be boiled before use. It should also be borne in mind that many weeds, such as dandelions, chickweed, groundsel and the seed-heads of other weeds may be used.

Bracken Meal.—Good results have been obtained with meals prepared from the dried young fronds and root stocks of bracken.

Heather Meal.—The leaves, flowering seeds and fine stalks of heather furnish useful food.

Couch Rhizomes.—The long, creeping underground stems of couch ("twitch") which give so much trouble in the cultivation of land in many districts, contain a considerable amount of useful food. They should be collected, washed, dried in the sun and cut into fine chaff, or, where facilities exist, ground into a meal.

In all cases where new or unusual foods are tried they should be introduced gradually, and the feeding modified according to the results obtained.

At the present time it is of little use to give any conventional recipes for mashies, as it is probable that the ingredients recommended would often be unobtainable.

One sample, however, of the successful use of garden waste is worth quoting—90 per cent. of cabbage leaves and 10 per cent. of meat meal were boiled together; the cabbage was then chopped fine, and the mash dried off with sharps or any meal obtainable.

In ordinary times it is generally accepted that a mash should not contain more than 25 per cent. of boiled vegetables, but it is obvious that during the summer the quantity must be exceeded when meals are unobtainable.

Owing to the scarcity of milling offals it appears probable that "dry mash" feeding must be abandoned.

Green Food.—All foodstuffs should be economised by liberal feeding of garden waste in its green state. In this respect lawn-clippings are valuable.

Points to be Noted.—(1) At a time like the present great care should be taken to ensure that nothing is wasted.

(2) Food given should be supplemental to that which fowls can obtain by foraging.

(3) After harvest, poultry should be given the run of the stubbles to enable them to utilise waste grain.

(4) All mashes should be fed in troughs.

(5) Grain, except where buried in the litter, should be fed in the same way.

(6) All foods should be stored in rat-and-mouse-proof bins or boxes, since these vermin cause great loss, not only consuming large quantities, but spoiling a great deal more than they eat.

(7) Sparrows, which are probably the biggest robbers of poultry food, should be kept down.

*This article is also issued in the form of Leaflet No. 114
as re-written.*

CONSIDERABLE shortage of poultry feeding stuffs is general, more particularly amongst those that go to form the largest

Notes on Poultry Feeding : bulk of the mash feeds during normal times.

From the Harper Adams Agricultural College, Newport, Salop. Sharps and bran are now entirely unobtainable in any quantity by the average poultry-feeder, which has necessitated increased replacement by substitutes.

Biscuit meal has also almost entirely disappeared from the market. Palm kernel meal has proved to be one of the most valuable ingredients of the mash for the replacement of the

cereal offals, as will be instanced by the following dietary, upon which it has been possible to maintain high laying capacity (up to 3,000 eggs per week) from 700 birds on grass runs :—

							<i>Price per cwt.</i>	
							<i>s.</i>	<i>d.</i>
Sharps	1 part	17	6
Bran	$\frac{1}{2}$	14	9
Fish meal	1	22	3
Compound meal	(chiefly							
palm kernel)	3	16	6
Maize meal	1	22	5
Clover meal	$\frac{1}{10}$	12	0*
Coarse ground oats	$\frac{1}{4}$	18	0
Meat meal	$\frac{1}{2}$	23	3

* Carriage forward.

The fall in the proportion of sharps from 55 per cent., as recorded in the last report,* to about 10 per cent. in the above mash formula, with the corresponding increase of palm kernel meal from 5 per cent. to about 30 per cent., are the most noticeable features of the present feeding.

Supplies of clover meal, while not showing any appreciable advance in price, have been more difficult to obtain in quantity, and this accounts for the reduction from about 11 per cent., as recorded in the previous report, to about 1 per cent. in the above mash. Reduction of clover meal during the present period is justified by the availability of plenty of young herbage at this season of the year, but in view of the value of this and similar (*e.g.*, alfalfa) meals, both for replacing green food and for maintaining the high protein content of the food of the laying hen, the increased production of leguminous and pulse crops by all poultry-keepers who have facilities for growing them is highly desirable during the present season.

Recent results obtained in the feeding of laying hens in New Zealand have shown that excellent results can be obtained in the matter of egg yield by the feeding of a ration containing up to about 25 per cent. of lucerne (or alfalfa) meal.

Attention was called in the previous report to the dustiness of many samples of clover meal offered for sale in this country. It is also noticeable that many supplies contain a large proportion of parts of non-leguminous herbage, chiefly stalks and seeds of many of the common grasses. Where such is the case, the value of the sample for purposes of poultry-feeding must be considerably reduced, the grasses having ripened before the time of cutting.

* This *Journal*, January, 1918, p. 1105.

In another case, involving 500 birds under large house conditions, the feeding has been on a different system, both dry and wet mash being used. The allowance of food has been strictly in accordance with the scale laid down of 4 oz. per head per day, including 1 oz. of grain. The egg yield under these conditions during March averaged for 500 birds of mixed breeds, 12 eggs per four weeks, and the money return per bird was 3s. 4d. The food consumed was 7 lb. per bird for four weeks at a cost of 1s. 5½d. Care was taken to make the utmost use of the grain by feeding in the litter each morning and well raking in. The later feeds of the day consisted of dry mash at noon and wet mash in the evening, using the same ingredients as set out in the mixture given above.

THE amount of feeding stuffs reaching the markets is still very limited, and market reports indicate that the situation

**Notes on Feeding
Stuffs in June:**

*From the
Animal Nutrition
Institute, Cambridge
University.*

as to supplies is not likely to be relieved during the coming month. Moderate quantities of palm nut cake, linseed cake and maize gluten feed and peas are to hand, and such supplies as are available should be reserved for the more important classes of stock.

The policy of the farmer should be directed to such modifications of his farming practice as will tend to make him more and more independent of purchased feeding stuffs, which should be regarded as adjuncts rather than essentials to any system of feeding practice.

In this respect, the possibilities of increased production of home-grown foods by the more extensive cultivation of forage crops and the use of silage should not be overlooked. An article dealing with this subject appeared in the March number of this *Journal* and should be consulted by persons interested.*

The system of allocation of concentrated feeding stuffs to the more essential classes of live stock by the system of Priority Certificates seems to be generally appreciated, and farmers on the whole have endeavoured to carry out in practice the policy indicated by the Board of Agriculture and the Ministry of Food. It is feared, however, that a small minority are still using feeding stuffs for other classes of stock than those covered

* See also p. 149 of this issue.

by the priority system, and it may become necessary to issue Orders constituting such action a penal offence.

The question of the provision of fodder, in view of the breaking up of extra grass land, and the demands of the Army, is an increasingly important one, and the farmer's energies should be directed to accumulating as far as lies in his power a big reserve for the coming year. A shortage in this respect would prove much more serious than the present deficiency of concentrated feeding stuffs, and by necessitating a considerable depletion in our live stock population would contribute far more towards the crippling of national efficiency than any amount of unrestricted U-boat warfare. Every endeavour should, therefore, be made to make up the deficiency of fodder, resulting from the decrease in acreage under grass, by the cultivation of quick-growing fodder crops in the coming summer months.

Horses.—Although agricultural horses are specifically exempted from the provisions of the Horses Rationing Order, farmers are strongly urged to see that their men do not exceed the rations there laid down. Although the scale there given is below what the men are accustomed to give in peace time, it is quite liberal enough to enable the horses to do their full work and to keep in good condition. When out to grass a considerable reduction in the feed given should be made. Copies of the Order may be obtained from the Controller of Horse Transport, 7, Whitehall Gardens, London, S.W. 1.

Milking Cows.—Experiments carried out at various Agricultural Colleges have shown that where cows are out to pasture, cake is unnecessary until after mid-July, even where the cows are fairly heavy milkers. Dairy farmers, therefore, need have no misgivings in refraining from the use of concentrated feeding stuffs until this period, and they should confine themselves to giving a little cotton cake in cases where the cows when turned out to grass show a tendency to scour.

Calves.—The small quantities of linseed and oats available for feeding live stock have made the question of obtaining satisfactory milk substitutes a difficult one. In view of this it may be of interest to state that the following mixtures have been successfully used in recent calf-rearing experiments,* when used in conjunction with whey. They are :—

1. A mixture of two-thirds by weight of oatmeal or fine thirds and one-third fish meal made into a porridge with boiling water and fed along with the whey.
2. Palm nut meal.

* West of Scotland Agri. Coll. Report, 1916-1917.

The calves were fed on whole milk for the first three weeks, and the whey and meal gradually introduced during the next three weeks, at the end of which period they were getting 1 gal. of whey and $\frac{1}{2}$ lb. of the mixed meals per head per day. From six weeks to three months the average consumption was $1\frac{1}{2}$ gal. of whey and 1 lb. of meal. The calves in addition were allowed to pick over fine hay and were given linseed cake after the eighth week.

Cattle for Beef Production.—No cake is available for bullocks, but on good pastures no difficulty will be met with in getting thriving two-year-olds ready for the butcher without cake.

Older cattle should run on the poorer grass land, ready to finish off next winter on roots and straw.

Yearlings should be kept over the winter on grass with a little hay for grazing in the summer of 1919, as the lack of cake will prevent the possibility of getting any ready for the butcher this year.

Sheep and Pigs.—The feeding of sheep and pigs has been fully discussed in recent numbers of the *Journal*.

Liquid Manure.—In view of the restricted supplies of nitrogenous manure every possible care should be taken of the liquid manure, especially on dairy farms.

Notes on Manures in June: Repeated analyses have shown the value of the liquid, and long experience of farmers and direct experiments by investigators alike prove its usefulness as a fertiliser. In cases where the drains from

*From the Rothamsted
Experimental Station,
Harpenden, Herts.*

the cow-sheds and stables run into a tank the system should be examined as early as possible so as to put it in order; if there is no tank an effort should be made to provide one. Probably 20 gal. per cow per week is a sufficient allowance for periods when the cows are in the shed all day, and of course a less amount when they are out of doors part of the time.

Salt for Mangolds.—Emphasis should be laid on the fact that salt in many cases increases the yield of mangolds, especially on rather light soils; experiments in the North (Cockle Park), the West (Harper Adams College), the Midlands (Woburn and Kingston) and the South (Rothamsted), have given favourable results. Fortunately, salt is a native product and can be obtained in this country in any desired quantity, though difficulty is sometimes experienced in obtaining delivery by

rail. The dressing to apply is 2 cwt. in the drills, and a further 1 cwt. top-dressing proved effective in the Midland agricultural trials.

Repair of Damage to Cereal Crops Done by Wireworms.—In cases where the plant is still alive but is being damaged by wireworms it may be helped to grow away from the attack by a dressing of quick-acting nitrogenous manure. Where the plant is nearly dead, this course cannot be adopted; some other plan must be tried, such as substitution of linseed, etc.

Bad Patches in Seed Leys May Indicate Lack of Lime.—Bad patches in the seed leys should be carefully examined as they may, and often do, indicate a lack of lime in the soil. Probably nothing can be done now, but the necessary lime, limestone or chalk should be laid in as early as possible so as to be ready for application in the autumn before the leys are ploughed up for the cereal crop. It is important that the utmost value should be got out of the residue of the ley ploughed in for the next year's corn crop, but this can only be done if sufficient lime is present in the soil. If the patches arise from the unsuitableness of the seeds mixture to the general climatic conditions it is desirable to change the formula and use a new mixture. If the crop does not look well after the first cut it should be ploughed up as soon after cutting as possible so as to get a long autumn fallow.

Buy London Stable Manure Early.—Potato growers in the home counties who are accustomed to use London stable manure in large quantities should buy early in view of the uncertainty of delivery, and clamp in the field where it is to be used next year. The clamp should be sheltered as much as possible from rain and sun, and it should be covered with a layer of earth. Summer storage of manure is undesirable as a general rule, but in this case it is probably the least risky course; it offers the advantage that the manure can be put into the land at the first ploughing in autumn, thereby facilitating decomposition of the manure and thus benefiting the crop, and also pushing forward some of the work, thus saving time in the spring.

Ash-pit Refuse.—In some parts of the country there are dumps of ash-pit refuse which may be useful manure. The only way of ascertaining their value is to have analyses made, and the accuracy of these will depend on the care with which the samples are drawn, which is by no means an easy task. If possible the county expert should be asked to arrange for the sampling so as to ensure a reasonable degree of accuracy.

THE following Note was published by the Food Production Department early in May :—

**Potatoes *versus*
Peas.**

It is difficult to lay down a hard and fast rule on the subject of the crops most suitable for growing by small cultivators.

Much depends upon the area of ground under cultivation, the difficulty or ease of transport for surplus produce, and the outlet for that surplus in the vicinity of the ground cultivated. Nevertheless, if the grower keeps in mind the broad fact of the situation that there is, and will be, a general scarcity, he can form for himself an intelligent opinion of the crops which it is worth his while to grow. Of these crops the potato stands easily first in the list.

At first sight it might seem that the bean and pulse crops, with their richness in nitrogenous food-proteins, should be increased largely in order to provide the only possible vegetable substitute for meat, and this view would seem to be supported when a comparison is made between the amounts of the essential foods contained in the bean and pulse crop, on the one hand, and the amounts contained in the potato on the other. These quantities are as follows :—

<i>Food.</i>	<i>Proteins.</i> Per cent.	<i>Fats.</i> Per cent.	<i>Carbohydrates</i> (<i>Starch, etc.</i>) Per cent.	<i>Calories.</i>
Dry Bean and Pulse Crops averages ..	23.1 ..	2.3 ..	53.6 ..	1,520
Potatoes ..	1.8 ..	0.1 ..	14.7 ..	310

From this table it might appear that bean and pulse crops, with their high percentage of proteins, would be much more profitable to grow in the present time of meat shortage than the potato, and the same conclusion would appear to be demonstrated by the fact shown in the last column that the food value as measured in food units or calories of a pound of bean and pulse crops is nearly five times as great as that in a pound of potatoes. But to draw such conclusions as these is to leave out of account one essential fact, namely, the relative yields per acre of these crops.

In order to judge the food value of a crop, yield per acre as well as chemical composition must be taken into consideration. We may assume that under garden conditions potatoes will yield 10 tons to the acre. The yield of dry bean or pulse seed cannot be put at more than 1 ton to the acre, and in the case of some of these crops it should be put at considerably less.

Reconstructing our table on the basis of yield per unit of area cultivated, we have the following :—

<i>Food.</i>	<i>Proteins.</i> Per cent.	<i>Fats.</i> Per cent.	<i>Carbohydrates</i> (<i>Starch, etc.</i>) Per cent.	<i>Calories.</i>
Dry Bean and Pulse				
Crops averages ..	23·1 ..	2·3 ..	53·6 ..	1,520
Potatoes	18·0 ..	1·0 ..	147·0 ..	3,100

This table reflects at a glance the fact that the potato crop beats the bean and pulse crops out of the field as a food crop, and that a given piece of ground under potatoes produces just about double the number of food units that are produced by an equal area under bean or pulse crops.

A good general rule to be followed by small cultivators is : Make sure of producing enough potatoes for your own requirements, help to supply any deficiency in the potatoes grown in your district by putting a further piece of ground under this crop, and then in the light of what has already been said use your discretion with respect to the growing of bean and pulse crops.

THE Departmental Committee appointed to consider the post-war position of the sulphuric acid and fertiliser trades as affected by the new acid plants, which have been erected during the War by the Ministry of Munitions for the Government, have just issued their Report, copies of which may be obtained from H.M. Stationery Office, Imperial House, Kingsway, W.C. 2., price 2*d.* net., excluding postage. The Ministry of Munitions, the Board of Agriculture, the Ministry of Food, and certain other Government Departments were represented on the Committee, as well as some of the most important Fertiliser Associations in the country, with Mr. Edward Shortt, K.C., M.P., in the Chair, and Mr. M. P. Applebey as the Secretary.

The Committee in their Report review the sulphuric acid trade before the War, and make recommendations as to the measures which should be taken in regard to the future output. The following are the principal points in the Report of interest to agriculturists :—

The Fertiliser Industries Before the War.—The production of sulphate of ammonia and of phosphatic manures before the

War provided the principal outlets for sulphuric acid, these two industries absorbing about 60 per cent. of the pre-war production.

The principal industrial sources of ammonia in the country are the carbonisation of coal and the distillation of shale. In each of these processes ammonia is an essential and a valuable by-product. In consequence of the progressive introduction of by-product coking the output of ammonia was steadily increasing, and at the outbreak of the War amounted to 400,000 tons per annum expressed as sulphate. About 15 per cent. of this production was not put on the market in the form of sulphate, but was converted into other ammonia products. The home consumption of sulphate of ammonia for agricultural purposes was only 60,000 tons per annum, and the remainder was mainly exported.

For some years before the War the manufacture of superphosphate in this country was in a very unsettled condition owing to the rapidly increasing importation of foreign manufacture and the gradual decline in the export trade. The export of superphosphates had reached a maximum of 160,000 tons in 1911, but had afterwards declined to 63,000 tons in 1913. The cause of this decline is to be sought partly in the erection of superphosphate plant in countries which previously imported this fertiliser, and partly in the competition of continental countries which, with the aid of cheap by-product acid from zinc manufacture, and in some cases with specially favourable freight conditions, succeeded in displacing their less favourably situated British competitors. This country possesses no natural advantages for the manufacture of superphosphates, since both pyrites and phosphate rock have to be imported as raw materials. It is, therefore, natural that when the consumption of superphosphate in countries such as Spain and Portugal reaches a certain point, local manufacture is undertaken, and, with the advantage of proximity to the raw material, soon succeeds in overcoming the competition of imported superphosphate from less favourably situated countries.

As in the case of sulphuric acid, the available plant was capable, if continuously worked, of producing considerably more than the actual requirements of superphosphate. The position with regard to manufacturing efficiency was somewhat varied. Most superphosphate works were associated with acid plants, and the larger producers were equipped with mechanical and labour-saving devices, which enabled them to

produce as economically as the continental works. Some of the smaller works, however, and especially those which had suffered from the loss of the export trade, had not been kept up to date, as the uncertain prospects of the trade led to unwillingness to incur outlay in development of plant.

One advantage which the fertiliser trades enjoyed was the existence of active and energetic trade associations. Both the Sulphate of Ammonia Association and the Fertiliser Manufacturers' Association were able to render valuable assistance to the individual producers, especially by organised propaganda, with a view to the creation and expansion of markets for their products.

The Fertiliser Industries During the War.—The expansion in the production of ammonia has during the War period been somewhat accelerated owing to its association with the by-product coking industry. The production of sulphate of ammonia has, however, suffered a temporary decline, owing to the diversion of large quantities of ammonia to the production of nitrate of ammonia. In view of the requirements of sulphuric acid for explosives manufacture, plants have been erected on a considerable scale for the conversion of crude ammonia into concentrated ammoniacal liquor. A substantial proportion of the requirements of ammonia for munitions purposes has thus been purchased in a form which requires no sulphuric acid for its manufacture. The total production of sulphate has thus been temporarily reduced from 350,000 tons to a little over 250,000 tons.

At the same time, there has been a large increase in the home consumption for agricultural purposes, owing to the substitution of this fertiliser for nitrate of soda, the entire supply of which has been required for explosives manufacture. The Board of Agriculture are understood to be aiming at the application of the entire available supply of sulphate to home purposes. The export trade has accordingly nearly disappeared, the only exports now allowed being relatively small quantities to allied countries and British Possessions.

The production of superphosphate has been very materially reduced during the War owing to the lack of sulphuric acid. From 1915, when the production of explosives on a large scale began, very large calls have been made on the output of the acid plant worked by the superphosphate makers. The production of superphosphate in 1916 fell to about 500,000 tons as compared with about 800,000 tons in 1913. During

the last few months, however, (*i.e.*, before February, 1918), the paramount necessity of increasing the home-grown food supply has been realised, and steps have been taken to secure a large and immediate production of superphosphate. Renewal and extension of superphosphate plant is accordingly proceeding at the present time with a view to recovering the lost ground as speedily as possible.

German Production of Nitrogen.—The following table shows the German production of nitrogen (calculated as sulphate of ammonia) :—

1913.		1917 (estimated).		Fixed Nitrogen.
480,000 tons	Sulphate of Ammonia ..	700,000	=	140,000 tons.
30,000 "	Cyanamide	400,000	=	80,000 "
20,000 "	Ammonia Haber ..	500,000	=	100,000 "
750,000 "	Nitrate of Soda Imports	nil.		—
				320,000 tons.

These processes may ultimately assume similar importance in this country, but as their success is conditional upon the provision of cheap power, and as the processes are as yet undeveloped here, they cannot be so important a factor as to influence to any marked extent the conditions immediately following upon the cessation of hostilities. On the other hand the introduction of synthetic methods for the production of nitric acid, which are now in early stages of operation, tends to diminish the consumption of sulphuric acid for the manufacture of nitric acid.

The Post-War Position.—The Committee are therefore agreed that the immediate increase in the consumption of acid after the War is almost wholly a question of the development of the superphosphate industry. They have accordingly considered evidence both from agricultural experts and from fertiliser manufacturers as to the probable post-war position. Though opinions differ as to the quantity of superphosphate which can be absorbed, the Committee find that the agricultural experts whom they have consulted are unanimous in the view that very considerably increased fertilisation of the soil by means of superphosphate is not only possible but is highly desirable in the national interest. It is evident from the opinion of these witnesses, quite apart from any question of manufacturing facilities, that the greatly extended use of phosphatic manures is both economically profitable and is essential for the efficient cultivation of the land. The extent to which such extended use will in fact take place depends mainly upon the agricultural policy of the Government. Mr. T. H. Middleton, Deputy

Director-General of the Food Production Department, who gave evidence as the representative of the Board of Agriculture, submitted to the Committee an estimate of the post-war increase of fertilisers which he regarded as reasonable on the assumption that 3,600,000 acres of arable land were added to the existing area in the United Kingdom and that a larger proportion of the grass land was manured. This estimate indicated that in Mr. Middleton's opinion an additional quantity of 620,000 tons of superphosphate and 629,000 tons of basic slag could with advantage be used. This increased quantity of superphosphate would correspond to the absorption of 200,000 tons of sulphuric acid.

The available supply of basic slag is not likely to approach the figure mentioned above, but as this phosphatic manure can to a considerable extent be replaced by superphosphate it is evident that a much larger quantity of superphosphate could be employed if it were available.

The question of the future export market for superphosphate is one in which it has been difficult to obtain any exact data. The export trade has declined for reasons already set forth, and fertiliser manufacturers themselves do not appear to anticipate any considerable revival. On the other hand, Dr. E. J. Russell has referred to the probability of an increased demand in Australia, South Africa, and India, and to the likelihood of an increased demand in Russia and Rumania. It is, however, at least uncertain whether British manufacturers would be able to compete in these markets with superphosphates produced on the spot, or in places so situated as to give advantages in transport over the British producer. It would, therefore, be unwise to count upon the export trade as a means of permanently reducing the surplus to any extent, although in the years immediately succeeding the War Belgium may be a large buyer.

Agricultural Policy.—In view of the proved agricultural need for the use of additional quantities of fertilisers the Committee are of opinion that the large surplus of sulphuric acid plant which will become available at the end of the War provides an opportunity of an altogether exceptional nature for the development of a vigorous agricultural policy in relation to the efficient cultivation of the soil. Having regard, therefore, to the guarantees which are given to the farmer under the Corn Production Act, they recommend that the powers provided by Section 9 of the Act should be widely used to enforce the adequate use of fertilisers. Any necessary measures should

at the same time be taken to secure the sale of fertilisers to the farmer at reasonably low prices.

The educational work of the Board of Agriculture in this direction should be continued and extended. The farmer is slow to adopt new methods. On this account the Committee are of opinion that no effort should be spared to bring home to him the importance and the economic and financial advantages of an increased use of fertilisers.

Recommendations.—Among the recommendations of the Committee may be mentioned the following, which should have considerable bearing on the supply of fertilisers after the War :—

(a) That arrangements should be made with shipping, railway and canal companies for cheap and adequate transport of raw materials, acid and fertilisers, and that cheap freights should be arranged for the carriage of fertilisers to any part of the Empire or any Allied or neutral country where an opening for a market may offer.

(b) That the representative Joint Committee which has been recommended in paragraph 18* should be formed at once, and that it should include representatives of such Government Departments as may be interested ; further, that its functions should be—

(1) To endeavour to secure the introduction of acid made in Government works to the market in such a manner as to produce a minimum of disturbance, having due regard to the interests of all the industries concerned, and

(2) To suggest means whereby the erection of new acid works to deal with the gases from zinc concentrates can be avoided.

THE Food Production Department (72, Victoria Street, London, S.W. 1) have made arrangements whereby sufficient

**Practical Hints on
Potato Spraying.**

sulphate of copper will be available for the spraying of the 1918 potato crop, provided that supplies are ordered forthwith. Last year many orders were placed so late that lack of transit facilities made it impossible to obtain delivery in time, and such difficulties will be intensified this year. Orders for soda crystals should also be placed without delay.

* Not here printed.

Prices of Copper Sulphate.—The prices for copper sulphate are as given in the enclosed statement, which includes the prices charged in April:—

<i>Date for Delivery.</i>	<i>Price.</i>
April, 1918	£50 per ton
May/August, inclusive, 1918	£52 „

{ f.o.r. at maker's works.

Quantity included in Sale, <i>ex</i> Shop or <i>ex</i> Store.	Date for Delivery, <i>ex</i> Shop or <i>ex</i> Store.	
	April.	May/August, inclusive.
	<i>s. d.</i>	<i>s. d.</i>
2 cwt. and over	55 0	56 0 per cwt.
56 lb. and over, but less than 2 cwt. ..	57 0	58 0 „
28 „ „ „ 56 lb. ..	59 0	60 0 „
8 „ „ „ 28 „ ..	0 7	0 7 per lb.
4 „ „ „ 8 „ ..	0 7½	0 8 „
1 „ „ „ 4 „ ..	0 8½	0 9 „

Bags of copper sulphate and soda remaining from last year should be *carefully weighed* before use and the *new instructions* for mixing appended hereto rigidly followed. The copper sulphate may be used if it has been kept in a dry place during the winter, but if possible fresh soda should be procured, any surplus from last year being used for domestic purposes (*not* cooking). Copper-sulphate bags should weigh 4 lb., and soda bags 5 lb.

Many growers already have spraying machines, but in view of the probable increase of the area under potatoes this year the existing stock of machines should be increased, and arrangements made by which growers may share the use of a machine. Arrangements have been made for the manufacture of a certain number of knapsack spraying machines, but when these have been disposed of, there is no prospect of any more being obtainable. The importance of ordering early will therefore be realised. The present cash price is 70s. but this may be increased shortly.

Prices of Soda Crystals.—The principal manufacturers of soda crystals will supply this product during the season of 1918 at £4 7s. 6d. net per ton in 2-cwt. bags, delivered to any station in England, Scotland and Wales, in 5-ton lots. In large cities and other approved centres, lots of 1 ton and upwards will be supplied at the same price. For lots of less than 1 ton, orders should be placed with local dealers.

The retail price of soda crystals sold from shop or store ought not to exceed the following :—

							s.	d.
56 lb.	3	6
14 "	1	0
7 "	0	6
1 "	0	1

The demand for soda crystals can only be met by the manufacturers if orders are placed immediately and delivery accepted as and when facilities offer. Horticultural associations, farmers, allotment holders and others should therefore make arrangements to combine their requirements, and to place orders at once with manufacturers or dealers for lots of 1 ton and upwards, and with dealers or retailers for small quantities.

Principal Manufacturers of Knapsack Spraying Machines.—

1. Messrs. Benton & Stone, Bracebridge Street, Birmingham.
- *2. Cooper, Pegler & Co., 24, Christopher Street, London, E.C.
3. Four Oaks Spraying Company, Four Oaks, Sutton Coldfield.
4. Messrs. W. T. French & Son, Ladywood, Birmingham.
5. Mackie & Co., Caversham Road, Reading.
6. Parkinson Stove Company, Stechford.
7. I. & W. Purser, Ltd., 15, Charles Street, Hatton Garden, London, E.C.
8. Stonehouse Works Company, West Bromwich.
9. United Brassfounders, Ltd., Holloway Head, Birmingham.

Available horse-power spraying machines should be utilised to the fullest extent.

Many farmers are reluctant to purchase requisites before they are needed, in the hope that prices may reach a lower level. There will be no advantage in waiting as regards spraying-machines and materials, however, for 1918. Delay in ordering now may result in failure to obtain supplies. Both machines and materials may be obtained through the usual trade channels.

There should now be no necessity to impress upon growers the fact that spraying pays. Continued experiments have shown that on an average of a series of years spraying has increased the yield of sound potatoes by approximately 2 tons per statute acre; while in a bad season the neglect of this operation often means the loss of a large proportion of the crop.

* This firm import the Vermorel "Eclair" machines, but although in this case existing specifications cannot be changed, the price will be 70s., less 15 per cent. to wholesale trade.

The Care and Use of Knapsack Spraying Machines.—Internal Pump Machines.—Remove spraying nozzle ; pump clean water through the hose in order to remove dirt ; wash the tank out thoroughly.

Oil the three bearings of the crank shaft ; rub the leather shoulder straps with oil to prevent cracking.

External Pump Machines.—Wash out as above ; oil all working parts. To secure the smooth working of the pump and prevent the washers from hardening rub them with oil after use ; to obtain access to the pump-washers unscrew the top of the pump-valve.

Unscrew the caps of the two screw-valves at the base of the machine ; clean and oil balls at frequent intervals.

For lubricating, use good machine oil ; do not use paraffin. If spare parts are needed order them at once.

When filling the machine pour the mixture carefully through the strainer to ensure that no particles of dirt get into the tubes and nozzles.

When the machine is on the back adjusted for use, before the tap is turned on, make several strokes with the pump in order to secure sufficient pressure to throw a very fine mist. Remember that it is necessary to coat both surfaces of the leaves with a fine film of the mixture.

Immediate steps should be taken to procure suitable wooden barrels for mixing purposes, and care must be taken to see that these are thoroughly clean. Tar or paraffin barrels should be carefully cleaned and all traces of tar removed.

Councils, allotment associations and other bodies should arrange for labour to be trained in good time so that the spraying will be carried out efficiently.

In an average season an approximation to the following dates for the first spraying of second early and main crop potatoes will probably be satisfactory.

Cornwall	}	June 15th—end of June.
Devon		N.B.—Spraying should be done the last week of May for early varieties in the Penzance district and the first week of June in other forward districts in Cornwall, Devon, and the Isle of Wight.
Dorset		
Isle of Wight and Hampshire		
Somerset		
S.W. Wales		
Glamorganshire	}	July 1st—July 8th.
Gloucestershire		
Monmouthshire		
N.W. Wales		
Sussex		
Wiltshire		

Berkshire	}	July 8th—July 15th.
Herefordshire		
Kent		
Oxfordshire		
Surrey		
Worcestershire	}	July 15th—July 31st.
Remainder of the country ..		

(In the north-eastern counties spraying should usually be deferred until the last week of July.)

The second spraying should generally be done about three weeks after the first. It will serve to cover the new foliage and to protect more completely that already sprayed. In the south-west of England it will often be found advisable to spray a third time, and this applies also to other districts in wet seasons when heavy rains are frequent.

Instructions for Making Burgundy Mixture.—The mixture should be carefully made, otherwise injury to the foliage may result. It is essential that all the soluble copper be precipitated by the addition of sufficient soda. Whilst adding the soda to the solution of copper sulphate the mixture must be vigorously stirred. The precipitate formed by the mingling of these two substances should be flocculent and should remain in suspension for a considerable time.

For Spraying $\frac{1}{3}$ acre (say 50 rods).

1. Dissolve 4 lb. of sulphate of copper in 5 gal. of water in a barrel capable of holding 40 gal., then make up to 35 gal.
N.B.—Iron or zinc vessels must not be used
2. Dissolve in another vessel in 5 gal. of water 5 lb. of washing soda (previously broken up into small pieces if necessary).
3. When the soda is *completely* dissolved, add (2) to (1), stirring vigorously meanwhile.

N.B.—Both copper sulphate and soda should be of fully 98 per cent. purity.

Where smaller areas are to be sprayed, barrels, capable of holding 10 gal., may be used; in that case the quantities of copper sulphate and soda given above should each be reduced to $\frac{1}{4}$, name y, 1 lb. of sulphate of copper and $1\frac{1}{4}$ lb. of washing soda.

Burgundy mixture should be bright blue in colour and should not settle for a considerable time. Experience has shown that the precipitate remains longer in suspension and adheres better to the foliage when the mixture is made up in the above manner than when the soda is added to a concentrated solution of copper sulphate. The fungicide should be

used in a *fresh state* and in no case should it be applied more than 10 hours after it has been made.

Sulphate of Copper is poisonous, therefore the vessels in which the copper compounds have been prepared should not be used for the preparation of food.

Opinions differ as to the relative value of Bordeaux and Burgundy mixtures; there is, however, no doubt that both are efficient fungicides. Where freshly-burnt stone-lime of good quality is to be obtained the use of Bordeaux mixture is to be recommended; but in districts where good lime is not readily to be had, Burgundy mixture should be used.

Instructions for Making Bordeaux Mixture.—This mixture should be made up in the following proportions:—

Copper sulphate	4 lb.
Quick lime (freshly-burnt lumps)	2 „
Water	40 gal.

The copper sulphate should be dissolved in 35 gal. of water in a barrel. The lime should be placed in a separate vessel and slaked *s'ow'y*. This is best done by adding only the amount of water which the lime can absorb. After the lime is thoroughly slaked, more water should be added gradually, stirring all the time, to make up to five gal. It should then be strained through a fine sieve and added to the solution of sulphate of copper, the contents of the barrel being vigorously stirred during the mixing.

Cultivation of Lands—Spraying of Potato Crops to Prevent Disease.—It is hoped that the councils of boroughs and urban and rural districts and parishes will help by purchasing spraying machines, if not already in possession of them, with the necessary chemicals, and hiring them out for use by the smallholders and cottagers in their respective districts. and, where possible, arranging for the spraying to be carried out by a competent operator. The Local Government Board will offer no objection to the incurring of the necessary expenditure, but they consider that a suitable charge should in all cases be made for the use of the machines.

This article is also issued as Food Production Leaflet No. 43, copies of which may be obtained free on application to the Board.

OFFICIAL NOTICES AND CIRCULARS.

N.B.—The Orders which may be mentioned in this section of the JOURNAL may usually be obtained at the price of 1d. each from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, and 28, Abingdon Street, London, S.W. 1; 37, Peter Street, Manchester; and 1, St. Andrew's Crescent, Cardiff.

THE following Circular, dated 12th April, 1918, has been addressed to County Councils and the Councils of Boroughs and Urban Districts in England and Wales by the Board :—

Regulations Governing the Compulsory Hiring of Land.

SIR,—I. I am directed by the President of the Board of Agriculture and Fisheries to refer to the Board's Circular Letter of the 16th May, 1908 (A. 168/C),* enclosing copies of the Regulations made by the Board as to the compulsory purchase and hiring of land for small holdings and allotments, and to say that the Board have made fresh Regulations governing the compulsory hiring of land.

2. Two copies of the Regulations are enclosed herewith.† Additional copies can be obtained, either directly or through any bookseller, from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, price 1d. each.

3. Apart from the amendments necessary as a result of the passing of the Small Holdings and Allotments Act, 1908, and the Agricultural Holdings Act, 1908, the new Regulations differ from the old by certain amendments in paragraphs 2 (c), 5 (1), 6, 19, 20, and the foot-note to the Form of Order for Compulsory Hiring contained in the Appendix, and your attention is particularly directed to these amendments.

4. With regard to the alteration in paragraph 5 (1), namely, the deletion of the last sentence, I am to say that it is not intended by this alteration of the Regulations that Councils should usually insert a date in the notice to treat which leaves a period substantially less than six months, the period originally prescribed, between the date of the service of the notice to treat and the date on which the tenancy of the Council is to commence. The amendment is only intended to meet cases which occur occasionally in which it is not found possible for the Board to confirm the Order in time to allow of such complete period of six months to elapse before the next date of entry consistent with the terms of the Order.

5. In specifying in the notice to treat the date on which the tenancy of the Council shall commence, the Council should bear in mind that before they can take possession the various interests have to be ascertained, and, in default of agreement, the valuation has to be made, and a decision has to be arrived at as to whether the notice to treat shall be withdrawn, and it is desirable that a reasonable notice should be given to the persons interested that possession will be required on the date specified.

6. The amendment of Regulation 20 enables a Council to obtain certain details of the valuation which a valuer has not hitherto been required to furnish, but not to require him to state the basis on which he has arrived at the amounts specified in respect of the several items.

I am, etc.,

(Signed) A. D. HALL,

Secretary.

THE following Memorandum (No. 120/M 1), dated 8th April, 1918, has been addressed to Agricultural Executive Committees, Horse Officers and Commissioners by the Food

Supply of Horse-Drawn Implements. Production Department of the Board :—

With reference to the Memorandum No. 106/M 1 of the 21st March, 1918, stating that the Department are in a position to supply horse-drawn implements, the following list shows the types of implements available. A limited number of each type only can be supplied. Applications should be sent in immediately and will be dealt with in the order in which they are received. These implements may be used for hire to farmers as well as for the purposes under F.P. 92. The Department are prepared also to consider the release of these implements for sale to farmers through local agents, who should make application direct to the Department stating precisely their requirements: any financial arrangements will, however, be made between the agent and the manufacturing firm.

Committees who have storage accommodation should make their applications with a view to their future requirements.

ENCLOSURE.

THE following Notice was issued by the Food Production Department of the Board in April :—

Tractor and Horse-Drawn Implements. In addition to the 3,500 tractors placed at the disposal of agriculturists during the past year, the Food Production Department has supplied County Committees with over 2,500 cultivators, pressers, and trailer boxes for use with the tractors. Moreover, the Department has consigned to Committees about 14,000 horse-drawn implements, including 4,800 ploughs, 2,800 harrows and drags, 2,300 rollers and pressers, 1,200 drills, 780 disc harrows, 1,400 cultivators, and 1,300 carts and lorries.

THE following Notice was issued by the Food Production Department of the Board on 12th April :—

Cruelty to Government Horses. Whilst recognising to the full the difficulties of the farmer confronted with a shortage of skilled labour on the one hand, and a shortage of feeding stuffs on the other, the authorities are making it clear that they will show no leniency to anyone guilty of negligence or cruelty to stock. The Food Production Department and the County Committees are taking a very strong line on the necessity of due care and proper feeding for the horses loaned to farmers by the Committees. Any suspicious case brought to official notice is immediately inquired into, and where the evidence seems to demand a prosecution this is promptly undertaken. There is no doubt that farmers generally are in complete sympathy with the drastic punishment of anyone misusing the Government horses; they realise that anything which tends to put these horses out of condition must cause injury to the farming community as a whole. The careless or cruel minority of farmers will be interested to learn that a Bedfordshire farmer who was found guilty of starving three horses, the property of the Bedfordshire Agricultural Executive Committee, has been sentenced to serve one month's imprisonment in the second division, to pay a fine of £25, and the costs of the proceedings against him both at Petty Sessions and at Quarter Sessions, to which he had appealed unsuccessfully from the judgment of the Court below.

THE following Memorandum (No. 139/M. 1) was addressed in April to Agricultural Executive Committees by the Food Production Department of the Board :—

Supply of Harvest Carts and Lorries. The Department have made contracts for the supply of tip-carts and four-wheeled lorries fitted with raves and harvest ladders for use in connection with Prisoner-of-War Centres and gangs under F.P. 92. It is proposed to supply these approximately in the proportion of three carts and lorries to every ten binders supplied. Committees should state as soon as possible the number of carts and lorries they desire to be supplied with, giving separately the number of each. The Department will have available more lorries than carts, and it may not be possible in each case to meet the precise requirements of the Committee; in that event there will be supplied whatever is at hand, although every effort will be made to meet the wishes of the Committee.

THE Food Production Department call attention to the recent statements by the Prime Minister and Mr. Prothero on the subject of the tenure of war-time allotments. The position is that in the case of land which has been taken for allotments under the Cultivation of Lands Order, the Government have promised that legislation will be introduced this Session which will render possible the retention of such land under the Defence of the Realm (Acquisition of Land) Act, 1916, at least until the autumn of 1920, unless it is shown to the satisfaction of the Board of Agriculture that the land is required at an earlier date for building or other public purpose. If any allotment

holders of such land have to be dispossessed on that account, the Board will compensate them for the loss of their crops.

The Government have also undertaken to consider whether it is possible to give similar security of tenure to allotment holders under private landlords, at least so long as the shortage of food continues, and also whether further facilities should be afforded for the provision of permanent allotments after the War; but in view of the state of public business it may not be possible to deal with these matters this Session.

THE following Notice was issued in May by the Food Production Department of the Board :—

Horticultural Advisory Committee. Mr. R. E. Prothero, President of the Board of Agriculture, has appointed a Horticultural Advisory Committee to advise the Board of

Agriculture and Fisheries on all questions connected with the promotion of market gardening, fruit-growing, and horticulture generally, and in particular with regard to the distribution of produce and the organisation of the trades connected with those industries in the situation created by the War.

The Committee will be constituted as follows :—

Representatives of the Board of Agriculture: Lt.-Col. Sir David Prain, I.M.S., C.M.G., C.I.E. (*Chairman*), Dr. F. Keeble, C.B.E., F.R.S., (*Deputy Chairman*), and Mr. A. G. L. Rogers.

Representatives of the Growers: National Fruit Growers' Federation, Messrs. W. Colthup, G. F. Glenney, W. G. Lobjoit, A. Marshall, L. Oakes, and E. S. Warwick; National Farmers' Union (Kent Branch), Messrs. Bernard Champion and A. J. Raynham; Horticultural Trades Association of Great Britain and Ireland, Messrs. A. G. Jackman and G. W. Leak; British Florists' Federation, Mr. G. Munro; Lea Valley and District Nurserymen and Growers' Association, Mr. Joseph Rochford; Market Gardeners, Nurserymen and Farmers' Association, Mr. A. J. Loeney (Worthing), and Mr. R. R. Robbins (Middlesex).

Representatives of the Distributors: National Federation of Fruit and Potato Trades Association, Messrs. Ernest Glover, A. S. Harper, and Thomas Major; London Fruit, Flower and Vegetable Markets Association, Mr. F. R. Ridley; London and Provincial Fruit Buyers' Association, Mr. James Bradnum; London and Home Counties Retail Fruiterers and Florists Association, Mr. E. L. Vinden; Fruit Preservers Association, Mr. W. R. Deakin;

Together with Fruiterers' Company, Mr. Stanley Machin; Gardeners' Company, Mr. Francis Agar; and Royal Horticultural Society. Rt. Hon. Lord Lambourne, C.V.O., and Sir Harry J. Veitch, F.L.S., V.M.H.

The Joint Secretaries of the Committee are Mr. G. P. Berry and Lieut. R. Wellington, M.C.

THE following Letter (No. 21/H.), dated 26th April, 1918, has been addressed to Horticultural Sub-Committees by the Food Production Department of the Board :—

Demonstrations and Exhibitions in Fruit and Vegetable Canning.

SIR,—I am directed by the Food Production Department to inform you that prior to the formation of your Sub-Committee the Department accepted the generous offer made by the British Commercial Gas Association, on behalf of numerous Gas

Companies throughout the country, which contained the promise of assistance in popularising the various methods of fruit and vegetable preservation by canning demonstrations and exhibitions and by distributing literature.

The Gas Companies are in many cases, prepared to undertake the organisation of demonstrations free of charge, or to place their premises and fittings at the disposal of your Committee for the purpose of displaying exhibits or giving demonstrations.

In several districts these Companies have already undertaken to organise demonstrations, and the Department desires your Committee to avail themselves of these offers of assistance wherever possible. Where the programme arranged for your county mainly covers the rural districts, and does not include demonstrations in large provincial towns where these Companies can render assistance, the Department are prepared, in approved cases, to send you a special Instructor to undertake demonstrations of this type, and if necessary to supply an exhibit of preserved produce in order to make an attractive display.

I am, etc.,

(Signed) G. F. MIDDLETON,
For Controller of Horticulture.

THE following Notice was issued by the Food Production Department of the Board early in May :—

**Fruit and Vegetable
Preservation.**

Persons intending to can or bottle fruit or vegetables this season are reminded by the Food Production Department that they should lose no time in giving their orders for the necessary cans or bottles or they may be disappointed through delay in delivery. Would-be purchasers of the bottles (or glass jars) should place their orders immediately with the nearest retailer, or with the retailer from whom they usually obtain articles of this kind, and not with the Food Production Department. Only in cases in which it is impossible to obtain supplies from retailers should the Department be approached in the matter.

On the other hand, the Food Production Department is receiving orders for the "Home Canner" (price, carriage paid, £6 10s.), and for cans to be used with the same, for the preservation of fruit or vegetables. It is very important indeed that orders for cans should be sent in without loss of time so that makers can ensure delivery before the opening of the conservation season. Cans are supplied in one or five-gross lots, the price per gross being as follows :—

		1-Gross Lots.		5-Gross Lots.
American 2 lb. Cans	..	33s. per gross	..	31s. per gross.
" 3 "	..	40s. "	..	37s. 6d. "
" 6 "	..	45s. " $\frac{1}{2}$ "		
		86s. " gross		

Order forms and pamphlets, with full instructions as to the use of the canner and cans, may be obtained on application to the Food Production Department, 72, Victoria Street, S.W. 1.

A number of leaflets on food preserving are also being distributed free by the Secretary, Board of Agriculture, 3, St. James's Square, S.W. 1. They include "Fruit Bottling for Small Holders" (Leaflet No. 250), and "Fruit and Vegetable Drying" (Food Production Leaflet No. 9).

During the last week in April 65 demonstrations in fruit-bottling, drying, and canning were given by representatives of the Food Production Department. Over 5½ millions of bottles have been ordered this season through retailers to date.

AN Order (No. 411), dated the 10th April, 1918, made by the Food Controller, contains the following main provision :—

The Potato
(Restriction) Order,
1918.

1. (a) Except under a licence of the Food Controller no person shall after 15th April, 1918, use or treat any potatoes or any product obtained from potatoes or any article containing potatoes or containing any such product except for the purposes permitted by this Clause.

(b) The permitted purposes, in the case of ware potatoes which are fit for human food, are seed or human food, and in all other cases are seed, human and animal food, and the manufacture of articles of human and animal food, but do not include the manufacture of spirits.

(c) Nothing in this Clause shall prevent the use or treatment for any purpose of potatoes or products of potatoes or articles containing potatoes or containing any such product which are unfit to be used for any of the permitted purposes.

AN Order (No. 445), dated the 17th April, 1918, has been made by the Food Controller to the effect that :—

The Potatoes
(Amendment) Order,
1918.

1. Clause 28 of the Principal Order* is hereby revoked; and the following Clause substituted :—

"28. The highest or maximum prices at which potatoes of the 1917 crop (other than seed potatoes sold as or for seed) may be sold by the grower thereof shall be as follows :—

	£	s.	d.
" (a) For potatoes delivered prior to 15th April, 1918	6	10	0
" (b) For potatoes delivered between 15th April, 1918, and 14th May, 1918, inclusive ..	7	0	0
" (c) For potatoes delivered after 14th May, 1918 ..	7	10	0

" Except that a grower of potatoes may sell quantities of less than 1 cwt. to consumers at a price not exceeding 1d. per lb."

2. Clause 37 (b) of the Principal Order is hereby revoked, and the following Sub-clause substituted :—

" (b) The amount actually paid or payable by the retailer for carriage and portorage to his shop except any amount included under Sub-clause (a) of this Clause."

3. The following Clause shall be inserted between Clauses 48 and 49 of the Principal Order :—

"48. (a) On every sale of potatoes except to consumers the seller shall after the 30th April, 1918, furnish the buyer with accounts, invoices or receipts giving full particulars of the quantities sold and the prices paid or payable."

* See this *Journal*, October, 1917, p. 765.

THE Food Controller has decided to extend the date for receiving tenders for forward contracts for the 1918 potato crop to the 31st May.

These contracts apply to potatoes grown on acreage planted in excess of that planted in 1916, provided that the 1917 acreage is maintained under potatoes. The contract price ranges from £6 to £7 in England and Wales, and from £5 10s. to £6 10s. in Scotland, according to time of delivery. Applications for forms of tender should be made to the Director of Vegetable Supplies (Contracts Section), 94-100, Cromwell Road, London, S.W. 7. (*National Food Journal*, 24th April, 1918.)

POTATO Traders in England and Wales who desire to sell potatoes by wholesale after 31st May should apply for the renewal of their certificates of registration not to the Ministry of Food, but to the National Federation of Fruit and Potato Trades Associations, Tavistock Hotel, Covent Garden, London, W.C. 2,

Potatoes Sold by Wholesale.

or to the Manchester Offices of the Federation, 306, Corn Exchange, Manchester, or else to Associations affiliated to the Federation. Scottish dealers should apply to one of the following associations:—Glasgow and West of Scotland Potato Trade Association, 135, Wellington Street, Glasgow; Edinburgh and East of Scotland Potato Trade Association, 34, North Bridge, Edinburgh; or the Perth, Fife and Forfar Potato Trade Association, 41, South Methven Street, Perth. Members of the Co-operative Wholesale Society should address their applications to the headquarters of the Society. (*Board of Trade Journal*, 2nd May, 1918.)

THE following Circular Letter (No. 29/S1), dated 9th May, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board:—

Silos.

DEAR SIR,—The Department is convinced of the importance of immediately encouraging the use of silage in the country, and to this end is prepared to assist agriculturists in the manner set out in the enclosed pamphlet.* It is intended that the drawings, which are being sent under separate cover and the enclosed specifications†, should remain at your offices open to inspection by anyone interested. The pamphlets are for distribution, and I trust that you will be able to hand them to landowners or farmers who are likely to make use of the offer of assistance by the Department. If you can dispose of more copies, I shall be pleased to send you as many as required.

Enquirers who are taking a serious interest and contemplate actually building silos, will be furnished with specifications and drawings on application to the Department.

It is anticipated that before the 1919 crops are cut, a very large number of silos will be applied for, and since building operations in war-time are fraught with unusual delays and difficulties, farmers making earliest application will naturally stand the best chance of getting their contract executed in time for next year's harvest.

I shall be pleased to send an officer from our engineering section to confer as to the choice of site and other matters with anyone who

* See p. 149 of this *Journal*.

† Not here printed.

is in your opinion seriously proposing to accept the Department's offer. I can, of course, rely upon you not to transmit any request for a personal visit unless there is a reasonable probability that a silo will be built as the result of it. Approximate prices are given in the pamphlet, and unless any enquirer is prepared for the necessary expenditure a visit from an officer of the Department will be a waste both of time and money.

Yours faithfully,
(Signed) LAWRENCE WEAVER,
Controller of Supplies.

THE following Circular Letter (No. 27/S 3), dated 29th April, 1918, has been addressed to local authorities in England and Wales under the Destructive Insects and Pests Acts, 1877 and 1907, by the Food Production Department of the Board :—

Wart Disease of Potatoes Order of 1918: SIR,—I am directed to state, for the information of your local authority, that it has been decided to take further steps for the control of Wart Disease of Potatoes, which at present constitutes a serious danger to the potato crop of the country.

With this object in view, a new Order,* a copy of which is enclosed, has been passed, and I am to invite your attention to the following points of special importance.

It will be observed that occupiers of land affected by the Order will no longer be required to procure licences if they wish to plant potatoes, except as indicated in Article 3 (2) of the Order.

Application to Existing " Infected Areas " and " Infected Premises."—The Order revokes all existing Orders relating to Wart Disease as from the 1st June, 1918, but areas which are infected areas for the purposes of the Wart Disease of Potatoes (Infected Areas) Order of 1914, and the district affected by the Wart Disease of Potatoes (Restricted Districts) Order of 1917, No. 1, will become " Infected Areas " under the new Order.

The provisions of the Order will also apply to all lands which at the commencement of the Order are " Infected Premises " for the purposes of the Wart Disease of Potatoes Order of 1914.

New Areas.—The practice of scheduling numerous small areas as " Infected Areas," and of declaring large numbers of gardens, allotments, and other pieces of land to be " Infected Premises " will be replaced, where the disease is common in districts of considerable extent, by the certification of much larger areas as " Infected Areas." At a later date it may even become necessary, in some instances, to include a whole county in an infected area, as in the case of the district specified in the First Schedule to the accompanying Order.

The provisions of the Order will also be applied to premises not included in an " Infected Area," on which outbreaks of Wart Disease occur in future.

Restrictions on Planting (Article 3).—On and after the 1st June next, no potatoes other than approved immune varieties may be planted in any land affected by the Order, and no occupier of such land will require a licence to plant these varieties, but an inspector of the Board may, in exceptional cases, issue licences authorising the planting of first

* See below.

early varieties susceptible to Wart Disease in land to which the Order applies. The exception relating to first early susceptible varieties is made in view of the limited quantity of first early immune varieties available, but it must not be assumed that licences will be granted, except for special varieties. As the stocks of first early immune varieties become larger the issue of such licences will be discontinued.

*Restrictions on the Sale of Approved Immune Varieties (Article 4).—*Seed potatoes of approved immune varieties may not be sold to any person but a dealer in seed potatoes except under the authority of a licence issued by the Board, and it is desirable that growers concerned, before purchasing their supplies, should ascertain whether the seller has received the requisite licence.

It is also important that dealers should bear this provision in mind, as a serious view will be taken of contraventions of the Order in this respect.

The exact procedure to be followed under this Clause will form the subject of a further communication.

*Restrictions on the Use of Potatoes Grown in an Infected Area.—*Under Article 5 of the Order it is provided that potatoes grown in an "Infected Area" must not be planted in land which is not in an "Infected Area." The Department attach great importance to compliance with this provision, as in the past the spread of Wart Disease has been due, in a considerable degree, to the planting of potatoes from infected land in soil which is free from the disease.

Notification of Disease.—It will be observed that, under Article 7 of the Order, not only the first outbreak of Wart Disease on any land must be notified to the Board or to an inspector, but that every recurrence must also be reported.

Notification of Order.—It is not anticipated that local authorities will be required to appoint additional officers for the purpose of carrying out any part of this Order, but Article 14 provides that the Order, and any certificate issued by the Board declaring an area to be an "Infected Area," shall be published by the local authority in accordance with any directions given by the Board. The Department desire that growers and others concerned shall be made fully acquainted with the provisions of this Order, and any certificate issued under the Order, and information on this subject, with the necessary directions, will be issued to local authorities from time to time.

I am, etc.,

LAWRENCE WEAVER,

Controller of Supplies.

By an Order (*The Wart Disease of Potatoes Order of 1918*), dated 10th April, 1918, applying to England and Wales, and which comes into operation on 1st June, 1918, the Board of

The Wart Disease of Agriculture and Fisheries order as follows:—
Potatoes Order of 1918. *Definition of Infected Area.*—2. (1) For the purposes of this Order the expression "Infected Area" means an area which is for the time being certified by the Board of Agriculture and Fisheries (in this Order referred to as "the Board") to be an area infected with Wart Disease for the purposes of this Order.

(2) The area described in the First Schedule to this Order, and also any area which at the commencement of this Order is an infected area for the purposes of the Wart Disease of Potatoes (Infected Areas) Order of 1914, shall, unless and until the Board otherwise certify, be an infected area for the purposes of this Order.

Restriction on Planting Potatoes in an Infected Area.—3. (1) No person shall plant, or cause or permit to be planted, in any land in his occupation or under his charge which is situated in an infected area, any potatoes which are not of an approved immune variety, and no person shall permit any potatoes to remain in land in his occupation or under his charge if the potatoes have been planted in contravention of this Article, and the removal of the potatoes is required by notice served on him by an inspector; provided that a person shall not be liable to conviction for planting potatoes or causing or permitting potatoes to be planted in contravention of this Article if he proves to the satisfaction of the Court that the potatoes were sold to him as potatoes of an approved immune variety by a person authorised by the Board under this Order to sell for planting potatoes of an approved immune variety, and that he did not know that the potatoes were not of an approved immune variety.

(2) The restrictions imposed by this article shall not apply to any planting which is licensed by an Inspector of the Board for the purpose of enabling a first early variety of potatoes to be grown.

(3) An approved immune variety is a variety approved for the time being by the Board as being immune from Wart Disease.

Restriction on Sale of Approved Immune Varieties.—4. (1) No person shall sell or offer for sale for planting, except to a dealer in seed potatoes, any potatoes of an approved immune variety unless he is authorised to do so by a licence granted by the Board, or in contravention of the conditions (if any) imposed by the licence, and no person shall sell as potatoes of an approved immune variety potatoes which are not of an approved immune variety.

(2) Any person who sells or offers for sale for planting (otherwise than to a dealer in seed potatoes) potatoes of an approved immune variety shall if so required by the person to whom the potatoes are sold or offered for sale produce the authority of the Board or a copy thereof for his inspection and permit him to copy the authority or copy.

Restriction on Use of Potatoes Grown in an Infected Area.—5. No person shall knowingly sell or purchase or use for planting in land which is not in an infected area any potatoes which have to his knowledge been grown in an infected area.

Application of Preceding Provisions to Land not in an Infected Area.—6. (1) An inspector may by notice served on an occupier or other person in charge of land not in an infected area on which the inspector is satisfied that Wart Disease exists, or to which in his opinion the disease is likely to spread, apply the preceding provisions of this Order to such land and such provisions shall, while such notice remains in force, apply to such land as if it were an infected area.

(2) The preceding provisions of this Order shall, without service of notice under this article, apply until they are withdrawn by an inspector, to any lands which at the commencement of this Order are "infected premises" for the purposes of the Wart Disease of Potatoes Order of 1914.

Notification of Disease.—7. (1) The occupier or other person in charge of any land on which Wart Disease exists or appears to exist, and any person having in his possession or under his charge potatoes which are affected with Wart Disease, shall forthwith notify the fact by post or otherwise to the Board or to an inspector.

(2) If Wart Disease is found to exist in any subsequent year on land in respect of which notification of disease has been given a further notification of disease shall be so given.

Sale of Diseased Tubers Prohibited.—8. Tubers visibly affected with Wart Disease shall not be sold or offered for sale for any purpose.

Precautions to be Adopted in Case of an Outbreak of Disease.—9. (1) An inspector may at any time and from time to time by notice served on an occupier or other person in charge of land on which the inspector is satisfied that Wart Disease exists require him to adopt such measures for the prevention of the spread of the disease as are authorised by this Article and specified in the notice.

(2) A notice under this Article may require the occupier or other person in charge of the land to adopt one or more of the following measures, that is to say:—

- (a) to destroy any part of the crop of potatoes, except the tubers, by fire or such other suitable method as may be specified in the notice;

- (b) to boil thoroughly all diseased tubers ;
- (c) to take such other steps as the inspector may consider necessary to prevent the spread of the disease.
- (3) Any such notice may appoint the time within which the adoption of any measure thereby prescribed shall be completed.
- (4) Nothing in this Article shall prevent the destruction by the owner, by fire or other effective method, of any tubers affected with Wart Disease.

Service of Notices, etc.—10.—(1) For the purpose of this Order a notice shall be deemed to be served on any person if it is delivered to him personally or left for him at his last known place of abode or business, or sent through the post in a letter addressed to him there ; and a notice purporting to be signed by an inspector shall be *prima facie* evidence that it was signed by him as an inspector.

(2) A copy of every notice served under this Order shall be sent to the Board by the inspector by whom the notice is signed.

(3) A notice served under this Order, which applies the provisions as to infected areas to premises which are not in an infected area, shall remain in force until its operation is determined in writing by an inspector of the Board.

Power to Deal with Diseased Potatoes.—11. An inspector may by a notice served on any person having in his possession or under his charge tubers which are affected with Wart Disease, or which are in a pit, bag or other receptacle with tubers so affected, or which the inspector has reason to believe to have been in a pit, bag or other receptacle with tubers so affected or otherwise exposed to infection with Wart Disease, prohibit the removal of the tubers from the premises on which they are when the notice is served, except under such conditions as the inspector may consider necessary to prevent the spread of Wart Disease and prescribe by the notice.

Information to be Given as to Diseased Potatoes.—12. Every person who has or has had in his possession or under his charge any tubers affected with Wart Disease, and every person who as auctioneer, salesman or otherwise has sold or offered for sale any such tubers shall, if so required in writing by the Board or an inspector, give the Board or the inspector, as the case may be, all such information as he possesses as to the persons in whose possession or under whose charge they are or have been : Provided that any information given under this Article shall not be available as evidence against the person giving the same in any prosecution under this Order, except in respect of an alleged failure to comply with this Article.

Powers of Entry.—13. An inspector, upon production if so required of his appointment, may for the purpose of enforcing this Order enter any land and examine any potatoes thereon.

Notification of Order.—14. This Order and any certificate issued by the Board thereunder shall be published by the Local Authority in accordance with any direction given by the Board.

Offences.—15. Every person shall be liable on conviction to a penalty not exceeding £10, who does any act in contravention of this Order, or fails to do any act which, by this Order or any notice served on him under this Order, he is required to do.

Revocation of Order.—17. (1) The Orders described in the Second Schedule hereto are hereby revoked ; provided that such revocation shall not :—

- (i.) affect the previous operation of any such Order or anything duly done or suffered under any such Order ; or
- (ii.) affect any right, privilege, obligation or liability acquired, accrued, or incurred under any such Order ; or
- (iii.) affect any penalty incurred in respect of any offence committed against any such Order ; or
- (iv.) affect any investigation, legal proceeding, or remedy in respect of any such right, privilege, obligation, liability or penalty as aforesaid ;

and any such investigation, legal proceeding or remedy may be instituted, continued, or enforced, and any such penalty may be imposed as if this Order had not been made.

(2) Every notice which requires an occupier to adopt measures for prevention of the spread of Wart Disease and which has been served under an Order hereby revoked shall have effect as if it were a notice duly served under this Order.

FIRST SCHEDULE.

Description of Infected Area.—The area comprising the administrative county of Glamorgan, the county boroughs of Cardiff, Swansea, and Merthyr Tydvil, the petty sessional divisions of Amman Valley and Llanelly, in the administrative county of Carmarthen, the petty sessional divisions of Ystradgynlais and Penderyn, in the administrative county of Brecknock, the petty sessional divisions of Bedwellty and Pontypool, and the parish of Risca, in the administrative county of Monmouth.

SECOND SCHEDULE.

ORDERS REVOKED.

<i>Date of Order.</i>	<i>Title of Order.</i>
2nd February, 1914 ..	Wart Disease of Potatoes (Infected Areas) Order of 1914.
2nd February, 1914 ..	Wart Disease of Potatoes of 1914.
15th January, 1917 ..	Wart Disease of Potatoes Order of 1917.
24th November, 1917 ..	Wart Disease of Potatoes (Restricted Districts) Order of 1917, No. 1.

All Orders declaring infected areas for the purposes of the Wart Disease of Potatoes (Infected Areas) Order of 1914 are revoked by this Order.

THE following Notice was issued by the Food Production Department of the Board early in May :—

Corn in Grass. Recently articles have appeared in several papers describing the experiment made by a South of England agriculturist in growing hay and corn together; corn being drilled into unploughed grass land, eaten off, and then allowed to grow again the following summer for reaping as a corn crop, a hay crop being taken from the same land in the same summer. The Food Production Department has been mentioned as being in some way or another associated with the experiment. Inquiry at the office of the Department, however, elicits the fact that nothing is known of the experiment except that it is still in a very early stage and that no results have yet been attained that would warrant the claims put forward. The experience of farmers in all parts of the country has shown that corn crops are injured by the competition of grasses (twitch, bent, etc.) during their growing period. About a year ago an application was made to the Department for a permit to manufacture a machine for this experiment, and the Department, not desiring to stand in the way of any experimental work which did not impose a burden on the national resources, raised no objection to the making of the machine in question. This circumstance, however, does not carry with it any endorsement of the remarkable claims lately put forward.

THE following Notice was issued in April by the Food Production Department of the Board :—

Sugar Beet: At the present time, when pig-keeping is so important and feeding stuffs are scarce and dear, small cultivators will be well advised to sow, where possible, a breadth of sugar beet as a source of food for stock, apart from its value as a sweetening agent.

Cultivation in Gardens and Allotments.

The crop may be sown on a variety of soils. The most suitable are deep, medium loams, while heavy clays should be avoided. Deep cultivation of the soil is in all cases essential.

Ordinary farmyard manure may be applied at the rate of from 10-12 tons per acre, with the addition of $1\frac{1}{2}$ cwt. of sulphate of ammonia ($\frac{1}{2}$ oz. per sq. yd., 1 lb. per rod) and from 3-4 cwt. of superphosphate per acre ($1-1\frac{1}{2}$ oz. per sq. yd., and $2\frac{1}{2}-2\frac{3}{4}$ lb. per rod) before sowing, or the sulphate of ammonia may be halved and one half held over and given as a top dressing after singling.

It is important that only the best strains should be grown; therefore seed should be purchased from reputable firms or obtained from the Secretary, British Sugar Beet Growers' Society, 14, Victoria Street, S.W. 1.

A good tilth is necessary at sowing time, and the seed is usually drilled on the flat, at distances of 16-18 in. between the rows, and 8-10 in. between the plants, or the small grower may adopt the dot system as recommended in the Food Production Leaflet No. 8; and thus a further economy in seed will be effected.

The rate of sowing is about 10-12 lb. per acre ($1-1\frac{1}{2}$ oz. per rod), and the best time to sow is the last week in April or first week in May. Constant stirring of the soil by the horse- or hand-hoe, as soon as the rows can be distinguished, tends greatly towards the production of a strong, healthy seedling.

Singling has to be done about 6 weeks after sowing. The crop is first roughly bunched by the hoe, and then singled by hand. Care should be taken in subsequent hoeings to damage the foliage as little as possible, as the crops yielding the largest sugar content are those which bear the best-developed leaf system.

The crop requires a long growing season, and should not be harvested prematurely, as the percentage of sugar increases to a marked extent during the final stages of ripening.

The lifting period extends from the end of September to the middle of November or a little later, according to the season. Ripeness is indicated by the leaves becoming yellowish-green in colour and drooping. About three-quarters of the foliage should have wilted, but the central leaves should still be fresh and green. The crop should be lifted and stored before there is any danger of hard frost, and only the tops removed by twisting.

Under ordinary conditions, a crop of 12 tons per acre may be expected, and there are instances on record where crops up to 18 tons have been obtained with an average of 16.5 per cent. of sugar.

For feeding purposes it is estimated that 4 lb. of good sugar beet are equivalent to 8 lb. of mangolds or 1 lb. of cereal meals in mixed rations. The leaves provide a valuable food for stock, and when dug into the ground their manurial value is high, and the effect can usually be seen on the subsequent rotation.

Numerous attempts have been made to utilise the roots for sweetening purposes, and the following recipes for the manufacture of syrup, which have been found satisfactory by private individuals, are appended:—

1. From Mrs. Smith.—Peel and scrape the beet and remove every particle of skin, then cut it in slices about $\frac{1}{2}$ in. thick. Cover with water for 2 hours, then simmer for 8 hours, or leave the vessel containing it in a hay-box all night—a hay-box is by far the best. Strain and bottle.

The syrup should be of a bright golden colour like golden syrup. In air-tight bottles it will keep a month, otherwise only a few days. Suitable for any kind of sweetening.

After straining the syrup chop the beet and dry it in a cool oven ; it can then be used in place of sultanas for cooking. If the pieces become very hard, soak them for 10 minutes in cold water before using ; if they remain fairly soft use them as they are. If the pieces are not required to be used as sultanas afterwards, the raw beet can be run through a mincing machine before cooking. This method of preparing the beet for syrup gives a much quicker result.

2. From Mr. Vincent Banks.—Clean and boil the beet until well cooked, then rub the skins off and cut into thin slices, and chop them up very fine. Put 2 pints of water in an enamelled saucepan and bring to the boil, then put 2 lb. of the chopped beet in, and boil with the lid on for three-quarters of an hour. Press the juice through a fine sieve and strain it through a thick cloth. Put the strained juice into a clean saucepan and bring to the boil, then add half a teaspoonful of bi-carbonate of potash. Keep boiling until reduced to one-third, pour into a hot bottle and cork at once.

Net weight of syrup about 6 oz.

For larger quantities simply multiply all the above according to requirements.

THE following Notice was issued in April by the Food Production Department of the Board :—

**The Cultivation of
Linseed as a Food
for Calves.**

Stock rearing is at present one of the farmers' many difficulties. Such milk as is not sold direct should be made into cheese and little, if any, is available for calves. The substitutes for milk formerly in use are, for various reasons, unprocurable. This being the case, the President of the Board of Agriculture and Fisheries wishes to urge as many farmers as possible to grow a small area of linseed.

As a food for calves the value of linseed is too well known to need recommendation. It is particularly rich in oil (35 per cent.) and in albuminoids (23 per cent.), and in these ingredients it far surpasses most other home-grown crops. A pound of linseed is for general feeding purposes equal to nearly 2 lb. of oats or $1\frac{1}{2}$ lb. of the best oilcake or cereal food.

In addition to this it is a crop that can be easily cultivated. A fine surface tilth and a light covering are all it needs. It is suited to most parts of the country and to most soils. It can be sown as late as the middle of May or even later. It is practically immune from wireworm, and may, therefore, be taken after old grass or used for filling up a thin corn crop or replacing one that has failed. When it is too late to sow barley, there is still time enough for linseed.

Stocks both of home-grown and plate linseed suitable for seed production are available. Particulars as to price and cultivation may be obtained from the Controller of Supplies, Food Production Department, 72, Victoria Street, London, S.W. 1.

THE following Notice was issued by the Food Production Department of the Board on 12th April :—

Growing Mangold Seed on the Farm. In view of the possible shortage of mangold seed next year, the Food Production Department suggest that farmers having a surplus of mangolds at the present time should consider the desirability of planting selected bulbs for seed production. Sound, medium-sized, well-shaped bulbs should be selected. The root should not have been touched by the trimming knife at lifting time. The ground should be prepared by deep tillage and liberal manuring, and the "bulbs" planted at least 2 ft. apart; if planted at a greater distance they suffer from beating by the wind. All roots planted should be sunk in the soil to their full depth, so that the crown shows just above the surface. The seed is usually ready for harvesting in September and may be threshed out by flail on a sheet or on the barn floor. A yield of about 8 lb. per rod (30½ sq. yd.) may be expected under favourable conditions.

A NOTICE on the cultivation of sunflowers was issued in April by the Food Production Department of the Board.

The Food Production Department has **Sunflower Cultivation:** directed the attention of owners and occupiers of land not in use for the growing of food crops to the sunflower, the seeds of which are valuable both as a source of oil and for poultry food, and information has already been received by the Department that a considerable area is being planted with this crop.

In view of the importance of securing the largest possible supply of sunflower seeds the Department makes a further appeal to owners of gardens, those in charge of parks and public gardens, nurserymen, and to small cultivators generally to devote any vacant land *unsuitable for food crops* to growing sunflowers.

Information on the best method of cultivation may be obtained free on application to the Food Production Department; and seed of the American giant strain of sunflower may be obtained at reasonable prices from seedsmen.

Those who undertake to grow sunflowers should bear in mind that the ash obtained from the plants after the seed has been harvested is, owing to its richness in potash, a manure of considerable value at any time and of great value in the present scarcity of potash manures.

The ash obtained from burning the sunflower stems, leaves and heads is rich in potash, and inasmuch as an acre of sunflowers produces from 2,500 to 4,000 lb. of top the total yield of potash is considerable. Wolff found 62 per cent. of potash in the ash; the American estimates, however, are lower: these allow 3,000 lb. of top and 160 lb. of ashes per acre of crop, which should contain upwards of 50 lb. of potash.

It is important that this valuable source of potash should be fully utilised; and to that end, after the seed crop has been gathered, the tops of the plants should be collected and burnt, care being taken to choose a dry day. The ash, which by reason of the potash which it contains is very caustic, should be stored in a dry place until required for use as manure for the potato or other root crop in the following year. The ash should be spread a little while before the potato crop is planted at the rate of from ½ to 1 oz. to the sq. yd. At present prices the value of the potash contained in the ash from 1 acre of sunflowers is about 33s. 6d.

THE following Circular Letter (No. 28/S4), dated 30th April, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Provision of Copper Sulphate and Soda for Potato Spraying. SIR,—The Department consider it essential that adequate supplies of copper sulphate and soda for potato spraying should be provided for growers in all parts of your county during the coming season. I am, therefore, to request you to be good enough to take the necessary steps to ascertain whether merchants in the county have placed orders with makers for the supply of these materials and are prepared to stock sufficient quantities to meet the increased demands which may be anticipated.

For your information I enclose copies of two Notices* which have been issued giving the prices at which sulphate of copper and soda crystals can be obtained together. A list of firms to whom applications for supplies should be addressed is also enclosed.

It is desirable that distribution should take place through the agency of merchants who have been in the habit of handling agricultural requisites rather than that the Supplies Sub-Committee should undertake distribution themselves. The Committee will, however, render a very important service if they will see that adequate supplies are held by merchants throughout the county.

I am, etc.,
(Signed) LAWRENCE WEAVER,
Controller of Supplies.

ENCLOSURES.

ON 27th April, the attention of potato growers was drawn by the Food Production Department to the importance of placing orders at once for copper sulphate for spraying potato crops. There is evidence of a large demand; and the supply of copper sulphate available is limited.

The maximum price fixed for sales of not less than 1 ton for delivery from May to August by makers, free on rail, is £52 per ton.

The maximum prices in the case of sales for delivery *ex* vendor's store, shop or *ex* warehouse, railway goods' yard or public wharf are :—

2 cwt. and over	56s. per cwt.
56 lb. but less than 2 cwt.	58s. „
28 „ „ 56 lb.	60s. „
8 „ „ 28 „	7d. per lb.
4 „ „ 8 „	8d. „
1 „ „ 4 „	9d. „

The cost of transport to consumer's premises may be added to these prices, which are net prompt cash for copper sulphate of standard quality, *i.e.*, not less than 98 per cent. purity.

Orders should be placed at once with local agricultural merchants, wholesale chemists or ironmongers; if any difficulty is experienced in obtaining supplies, growers should communicate with the Food Production Department, 72, Victoria Street, S.W. 1.

* The Notice on prices of soda crystals is not here printed; particulars are given in the article on Potato Spraying on p. 198.

[Copper Sulphate and Soda Crystals. **MERCHANTS** wishing to obtain supplies should be advised to apply to one of the following firms :—

Copper Sulphate.

The Mond Nickel Co., Ltd...	39, Victoria Street, London, S.W. 1.
James H. Dennis & Co., Ltd.	24, Chapel Street, Liverpool.
McKechie Brothers, Ltd. . .	Ditton Road, Widnes, Lancs.
Vivian & Sons, Ltd... ..	Bond Court House, Walbrook, London, E.C. 4.
The United Alkali Co., Ltd.	30, James Street, Liverpool.
Spencer Chapman & Messel, Ltd.	36, Mark Lane, London, E.C. 3.

Soda Crystals.

Brunner Mond & Co., Ltd. . .	Silvertown, E.
The United Alkali Co., Ltd.	30, James Street, Liverpool.

THE following Memorandum was issued to the Press by the Press Bureau on 30th April, 1918 :—

**Fertiliser Prices
Order, 1918:
Memorandum.**

The Minister of Munitions has made an Order,* dated 30th April, and taking effect as from 1st May, relating to superphosphate, sulphate of ammonia, and ground basic slag.

The Order supersedes previous Orders relating to superphosphates of 20th August, 1917, 17th November, 1917, and 28th March, 1918, as regards sales after 1st May for delivery after 31st May, and regulates trade, fixes maximum prices, and equalises the cost of distribution of the fertilisers by rail or water throughout the United Kingdom.

The Order operates independently of the Fertilisers and Feeding Stuffs Act, 1906. The provisions of the Order as regards maximum prices chargeable do not apply to fertilisers sold for export (other than to Channel Isles or Isle of Man), sales of less than 14 lb., sales for delivery prior to 1st June, or sales of sulphate of ammonia for use in the manufacture of munitions or for industrial purposes.

Licences are required for the sale of fertilisers and for their dispatch under certain conditions. Makers, dealers and users must render such returns as are required.

" Superphosphate " means superphosphate of lime, manufactured from mineral phosphates, but does not include basic superphosphate, bone superphosphate, dissolved bones, bone meal, bone compound, guano, or compound manures, and sulphate of ammonia used for manufacture of compound fertilisers is deemed used for fertilising and not industrial purposes.

The scheme for equalising costs of distribution is contained in the Fifth Schedule to the Order, which provides for the opening by every maker or producer of the fertilisers of an account with the Government, wherein the Government is to be debited with the costs of carriage by rail or water incurred by the maker, and credited with a fixed sum of 12s. 6d. per ton (allowed for in the maximum prices fixed by the Order and meant to cover the estimated average cost of distribution), the difference being borne by the Government.

* Printed below.

Applications for licences relating to sales and consignments of superphosphates, ground basic slag and sulphate of ammonia to be used as fertilisers, and communications relating to the scheme for equalising costs of distribution should be addressed to the Food Production Department, Board of Agriculture and Fisheries, 72, Victoria Street, S.W. 1.

All other applications in reference to the Order and for licences for sale of sulphate of ammonia to be used in manufacture of munitions of war or for industrial purposes, should be addressed to the Director of Acid Supplies, Ministry of Munitions, Explosives Supply Department, Storey's Gate, Westminster, S.W. 1.

THE Minister of Munitions considers it necessary to regulate sales and purchases of superphosphate, sulphate of ammonia, and ground basic slag (in particular by fixing maximum

**Fertiliser Prices
Order, 1918.**

prices at which sales may be effected); also to provide for equalising, so far as possible, the cost of distribution of the said fertilisers by rail or water throughout the United Kingdom, and, for this purpose, to prohibit sales of the same by makers or producers for transport by rail or water, except on a delivered basis and at delivered prices, including, in every case, a fixed sum per ton to cover the estimated average cost of distribution, and to be accounted for by the makers or producers to the Minister or any other Government Department nominated by him for the purpose, by whom any costs of distribution by rail or water in excess of such estimate will be borne.

The Minister of Munitions has therefore made the following Order (*The Fertiliser Prices Order, 1918*), dated 30th April, 1918:—

1 This Order shall take effect as on and from the 1st May, 1918.

2. For the purposes of this Order the maximum prices for superphosphate, sulphate of ammonia, and ground basic slag respectively shall (except as hereinafter otherwise expressly provided) be as follows:—

(a) In the case of sales of any of the said fertilisers for delivery in railway trucks at purchaser's or consumer's siding or nearest railway station, or free *ex* barge or ship at purchaser's or consumer's wharf or other available wharf approved by the purchaser, or, in the case of shipments to the Channel Islands or the Isle of Man, *f.o.b.* at port of shipment, or, in the case of shipments of ground basic slag to Ireland, *c.i.f.* at Irish port, the following prices, namely:—

(i.) In the case of all sales (other than sales, by makers or producers, of smaller quantities than two tons) the respective prices specified in the First, Second and Third Schedules hereto for superphosphate, sulphate of ammonia and ground basic slag, respectively, according to the date on which, under the terms of the contract for sale, delivery is to be made, and to the description and quality of the fertiliser delivered, but with the addition, in the case of sales of ground basic slag for delivery in Ireland (otherwise than *c.i.f.* Irish port), of all charges incurred in delivering the ground basic slag from the ship in port of arrival in Ireland to place of delivery, any charges for cartage, haulage or warehousing of such ground basic slag or other services to be charged at not exceeding local rates.

(ii.) In the case of sales, by makers or producers, of any of the said fertilisers in smaller quantities than two tons, the same prices as those specified under paragraph (d) of this Clause for sales of the same fertiliser in similar quantities *ex* vendor's store or shop or *ex* warehouse.

(b) In the case of sales for delivery at maker's or producer's works free into road vehicles provided by the purchaser or consumer for conveyance direct by road to purchaser's or consumer's premises, the following prices, namely :—

of smaller quantities than two tons) the prices specified in sub-paragraph

(i.) In the case of all sales (other than sales, by makers or producers, (i.) of paragraph (a) above, less 10s. per ton.

(ii.) In the case of sales, by makers or producers, of smaller quantities than two tons, the same prices as those specified under paragraph (d) of this Clause for sales of the same fertiliser in similar quantities *ex* vendor's store or shop or *ex* warehouse.

(c) In the case of sales for delivery direct by road from maker's or producer's works to purchaser's or consumer's premises in road vehicles provided by the maker or producer, the prices specified under paragraph (b) above with the addition of the cost of cartage or haulage from the works to the purchaser's or consumer's premises, to be charged at not exceeding local rates.

(d) In the case of sales for delivery *ex* vendor's store or shop, or *ex* warehouse (other than maker's or producer's store or warehouse at point of manufacture), the prices specified under sub-paragraph (i.) of paragraph (a) above, with the addition of the following amounts, according to the quantity of superphosphate, sulphate of ammonia, or ground basic slag (as the case may be) included in the sale :—

Quantity Sold.				Additional Price Authorised.	
1 ton and over	10s. per ton.
2 cwt.	..	but less than 1 ton	1s. per cwt.
1	2 cwt.	..	2s. ..
28 lb.	1	3s. ..
14	28 lb.	..	4s. ..

and with the addition also (in the case of sales for delivery *ex* vendor's store or shop, where such store or shop is distant more than 2 miles from the nearest railway station or wharf available for the delivery of the fertiliser in railway truck, ship or barge) of the extra cost of carting or hauling the fertiliser by road from such railway station or wharf to such store or shop over the cost of carting the same a distance of 2 miles, such cost to be charged at not exceeding local rates.

(e) In the case of sales for delivery *ex* railway goods yard or public wharf, the prices specified under sub-paragraph (i.) of paragraph (a) above, with the addition of 2s. 6d. per ton in the case of sales of one ton or less, but without any addition in the case of sales of more than one ton.

(f) In the case of sales for delivery direct by road or barge from vendor's store or shop, or from warehouse, railway goods yard, or public wharf to consumer's premises, the prices authorised under paragraphs (d) and (e) above for sales of the same fertiliser in similar quantities *ex* such store, shop, warehouse, yard, or wharf, plus the cost of cartage, haulage or barging, to be charged at not exceeding local rates.

The above prices (other than those authorised under paragraphs (b) and (c)) include, in every case, a sum of 12s. 6d. per ton to cover the estimated average cost which will be incurred by makers and producers in distributing the said fertilisers by rail or water throughout the United Kingdom (or in the case of ground basic slag throughout England, Scotland, and Wales, and to Irish ports), which sum of 12s. 6d. per ton shall be accounted for in every case by makers and producers receiving the same as hereafter provided.

3. On sales of two tons or upwards by makers or producers to manure mixers, agricultural merchants or dealers, or co-operative companies or societies incorporated or registered under the Industrial and Provident Societies' Act, or any other Act, the maximum prices fixed by Clause 2 of this Order shall be reduced by a discount or allowance to the purchaser of

5s. per ton in the case of superphosphate,	
10s. " " " sulphate of ammonia,	
5s. " " " ground basic slag.	

4. The maximum prices fixed by the foregoing provisions of this Order are net cash prices for superphosphate, sulphate of ammonia, and ground basic slag, in maker's or vendor's bags, net weight excluding weight of bags. Where credit is given to the purchaser a reasonable extra charge may be made, provided that the discount allowed for net cash is quoted on the invoice and is such as to bring the net cash price within the maximum authorised. If purchaser's bags or other packages are used, or the purchaser takes delivery in bulk without bags, a reasonable allowance shall be made to the purchaser. Where 1 ton or upward is sold for delivery in bags containing less than 2 cwt. each, a reasonable extra charge may be made beyond the maximum prices which would otherwise have been authorised.

5. As on and from the date on which this Order takes effect no person shall sell or purchase, or offer to sell or purchase any superphosphate, sulphate of ammonia, or ground basic slag, except for delivery as specified in one or other of the sub-paragraphs of Clause 2 of this Order, and at a price not exceeding that prescribed by this Order and the First, Second, and Third Schedules hereto respectively as the maximum price for such sale, having regard to the description and quantity of the fertiliser sold, quality, packages, and date for and terms of delivery; nor shall any maker or producer of superphosphate, sulphate of ammonia, or ground basic slag, sell any of the said fertilisers for delivery as mentioned in paragraphs (a), (d), (e), or (f) of Clause 2 of this Order, without bringing into account and dealing with the sum of 12s. 6d. per ton (included in the prices authorised by such paragraphs to be charged on such sales) in manner specified in the scheme for equalising costs of distribution of superphosphate, sulphate of ammonia, and ground basic slag, set out in the Fifth Schedule hereto. Provided that:

(a) A vendor of superphosphate, sulphate of ammonia, or ground basic slag shall not be liable to conviction for selling at a price in excess of the maximum price prescribed by this Order for such sale, if the invoice given to the purchaser, as required by Clause 6 of this Order, states accurately within the limits of error specified in the Fourth Schedule hereto, the percentage of phosphate rendered soluble in water, ammonia, or total phosphate (as the case may be), contained in the superphosphate, sulphate of ammonia, or ground basic slag sold, and the price charged and stated on such invoice does not exceed the correct maximum price on the basis that the percentage stated in such invoice is correct; and

(b) A purchaser of superphosphate, sulphate of ammonia, or ground basic slag shall not be liable to conviction for purchasing at a price exceeding the maximum price, unless the price agreed to be paid by him is to his knowledge in excess of the maximum price authorised for such purchase.

6. As on and from the date on which this Order takes effect no person shall sell any superphosphate, sulphate of ammonia, or ground basic slag, without giving to the purchaser, on or before or as soon as possible after delivery, an invoice stating accurately within the limits of error specified in the Fourth Schedule hereto:—

(a) In the case of superphosphate the percentage (calculated in terms of tri-basic phosphate of lime) of phosphate rendered soluble in water, contained in the superphosphate delivered.

(b) In the case of sulphate of ammonia the percentage of ammonia (NH_3) by weight contained in the sulphate of ammonia delivered; and

(c) In the case of ground basic slag, the percentage (calculated in terms of tri-basic phosphate of lime) of total phosphate contained in the basic slag delivered.

and also, in the case of all three fertilisers, stating the price charged, together with any further particulars required to be stated on such invoice by any of the provisions of this Order or the Schedules hereto.

7. None of the foregoing provisions or restrictions of this Order as regards maximum prices chargeable or otherwise shall apply to—

(a) Any sales of superphosphate, sulphate of ammonia, or ground basic slag, for export from the United Kingdom to any country other than the Channel Islands or the Isle of Man.

(b) Any sales of any of the said fertilisers in quantities less than 14 lb.

(c) Any sales of any of the said fertilisers for delivery prior to the 1st June, 1918.

(d) Any sales of sulphate of ammonia for use in the manufacture of munitions of war or other industrial purposes.

8. As on and from the date on which this Order takes effect, the provisions of the scheme for equalising costs of distribution of superphosphate, sulphate of ammonia, and ground basic slag set out in the Fifth Schedule hereto, shall be binding upon all makers or producers of superphosphate, sulphate of ammonia, or ground basic slag, and upon the Minister of Munitions, or any other Government Department to which, by arrangement with the Minister of Munitions, the carrying out of the said scheme may be delegated; and any balances becoming payable by any such makers or producers to the Minister of Munitions, or any other such Government Department as aforesaid, under the provisions of such scheme shall be recoverable as Crown Debts.

9. As on and from the date on which this Order takes effect—

(a) No person shall sell (for delivery on or after the 1st June, 1918) any sulphate of ammonia which is to be used in the manufacture of munitions of war or for other industrial purposes, except under a licence issued by or under the authority of the Minister of Munitions, and in accordance with any terms and conditions of such licence as to quantity, price, mode of delivery, or otherwise.

(b) No person shall sell any superphosphate or ground basic slag, or any sulphate of ammonia which is to be used for fertilising purposes, for delivery on or after the 1st June, 1918) in railway trucks at purchaser's or consumer's siding or otherwise as mentioned in paragraph (a) of Clause 2 of this Order, except under and in accordance with the terms and conditions of a licence issued by or under the authority of the Minister of Munitions, or any other Government Department or body nominated by him for the purpose.

(c) No maker or producer of superphosphate, sulphate of ammonia, or ground basic slag shall, except under and in accordance with the terms and conditions of a licence issued as mentioned in paragraph (b) of this Clause, either (i.) sell to any person any superphosphate or ground basic slag, or any sulphate of ammonia which is to be used for fertilising purposes, for delivery (on or after the 1st June, 1918) ~~at~~ railway goods yard or public wharf, or (ii.) sell any of such fertilisers for delivery (on or after that date) as mentioned in paragraphs (b) or (c) of Clause 2 of this Order to any person other than a consumer purchasing the same for consumption on his own premises.

(d) No person shall, except under and in accordance with the terms and conditions of a licence issued as mentioned in paragraph (b) of this Clause, consign or despatch any superphosphate or ground basic slag (or any sulphate of ammonia which is to be used for fertilising purposes, by rail (other than light railway) to or for delivery to any person in smaller quantities than 4 tons, otherwise than as part of a consignment of not less than 4 tons of goods made from the same point of departure to same final railway destination at the same time.

10. All persons engaged in producing, manufacturing, selling, distributing, or storing superphosphate, sulphate of ammonia, or ground basic slag, or in any manufacture in which the same or any of them are used, shall make such returns with regard to their businesses, and shall verify the same in such manner (including production of their books to any accredited representative of the Minister of Munitions), as shall from time to time be required by or under the authority of the Minister of Munitions.

11. This Order and the Fertilisers and Feeding Stuffs Act, 1906, shall operate and have effect independently of one another, and nothing contained in this Order shall be held to exempt any person from compliance with any of the provisions or requirements of such Act, or any Regulations made thereunder, applicable to sales or purchases of superphosphate, sulphate of ammonia, or ground basic slag: nor shall any of the provisions of the said Act or Regulations be held to govern or affect any of the requirements or provisions of this Order, or any proceedings instituted in respect of any breach hereof.

12. This Order supersedes the Orders relating to superphosphates, made by the Minister of Munitions on the 20th August, 1917, the 17th November, 1917, and the 28th March, 1918, respectively, so far as regards all sales of superphosphate, for delivery on or after the 1st June, 1918, made on or after the date on which this Order takes effect.

13. For the purposes of this Order "superphosphate" shall mean superphosphate of lime manufactured from mineral phosphate, but shall not include basic superphosphate, bone superphosphate, dissolved bones, bone meal, bone compound, guano, or compound manures; and sulphate of ammonia used for the manufacture of compound fertilisers shall be deemed to be used for fertilising purposes, and not for industrial purposes.

14. This Order may be cited as the Fertiliser Prices Order, 1918.

FIRST SCHEDULE.

Maximum Prices for Superphosphate.

Percentage (calculated in terms of tri-basic phosphate of lime)
of phosphate rendered soluble in water.

		<i>Price per ton.</i>		
		£	s.	d.
15 per cent. and over, but less than 16 per cent.	..	4	12	0
16 "	" "	4	15	0
17 "	" "	4	17	6
18 "	" "	5	0	0
19 "	" "	5	2	6
20 "	" "	5	5	0

42 "	" "	8	18	0
43 "	" "	9	2	0
44 "	" "	9	6	0

The above prices for all qualities are the maximum prices for sales of superphosphate for delivery during December, 1918. The maximum prices

for sales of superphosphate for delivery during June, 1918, will be those fixed by the Superphosphate Order of the 20th August, 1917,* namely 5s. per ton more than the prices set out above, whilst in the case of sales of superphosphate for delivery during other months, the maximum prices for all qualities will be 1s. 6d. per ton per month less or more than the prices set out above, according as the month for delivery precedes or is subsequent to December, 1918, but with a maximum decrease or increase of 7s. 6d. per ton, e.g., the prices for July, 1918, deliveries will be 7s. 6d. less per ton, while the price for May, 1919, deliveries will be 7s. 6d. more per ton than the prices set out above.

SECOND SCHEDULE.

Maximum Prices for Sulphate of Ammonia containing 24½ per cent. by weight of Ammonia (NH₃).

<i>Date of Delivery.</i>	<i>Price per ton.</i>		
	£	s.	d.
1st June to 31st August, 1918, inclusive	15	5	0
1st September to 30th November, 1918, inclusive ..	15	15	0
1st December, 1918, to 28th February, 1919, inclusive	16	5	0
1st March to 31st May, 1919, inclusive	16	15	0

For sulphate of ammonia containing more than 24½ per cent. by weight of ammonia, the above maximum prices shall be increased by 3s. 3d. per ton for each complete one-fourth of 1 per cent. (calculated on the total weight of the sulphate of ammonia) by which the ammonia contents are more than 24½ per cent., whilst for sulphate of ammonia containing less than 24½ per cent. by weight of ammonia the above maximum prices shall be reduced by 3s. 3d. per ton for each one-fourth of 1 per cent. or fraction of one-fourth of 1 per cent. (calculated as aforesaid), by which the ammonia contents are less than 24½ per cent.

For sulphate of ammonia containing less than 0.025 per cent. of free acid an additional charge at the rate of 5s. per ton may be made by the vendor, provided that the invoice given by the vendor to the purchaser states such additional charge separately, and contains a guarantee by the vendor that the free acid contained in the sulphate does not exceed 0.025 per cent.

For sulphate of ammonia which is specially ground or pulverised at the request of the purchaser an extra charge (not exceeding 5s. per ton) may be made for special grinding, provided that such extra charge is separately stated on the invoice given to the purchaser as aforesaid.

The above increases or reductions in the maximum prices chargeable shall not apply to any sale of less than 2 cwt. of sulphate of ammonia.

THIRD SCHEDULE.

Maximum Prices for Ground Basic Slag.

Percentage (calculated in terms of tri-basic phosphate of lime) of total phosphate.

		<i>Price per ton.</i>		
		£	s.	d.
12 per cent. and over, but less than	14 per cent. ..	3	0	0
14	16	3	2	0
16	18	3	4	0
18	20	3	6	0
20	22	3	8	0
22	24	3	10	0
24	26	3	13	0
26	28	3	16	0
28	30	3	19	0
30	32	4	2	0
32	34	4	5	0
34	36	4	8	0
36	38	4	11	0
38	40	4	14	0
40	42	4	17	0
42	44	5	0	0

The above prices for all qualities are the maximum prices for sales of ground basic slag for delivery between September 1st, 1918, and 28th February, 1919.

* See this *Journal*, September, 1917, p. 686.

In the case of sales of ground basic slag for delivery during other periods, the maximum prices for all qualities will be less than the prices set out above, in accordance with the following table, namely :—

<i>Period for Delivery.</i>	<i>Reduction in the Maximum Prices set out above.</i>
During June, 1918	4s. per ton.
„ July, 1918	3s. „
„ August, 1918	2s. „
From 1st September, 1918, to 28th February, 1919	Nil.
During March, 1919	2s. per ton.
„ April, 1919	3s. „
„ May, 1919	4s. „

The above prices for all qualities are for basic slag ground in such a way that at least 80 per cent. of the total weight will pass through a sieve containing 10,000 apertures to the square inch. Where basic slag is sold less finely ground, an allowance off the above maximum prices shall be made to the purchaser at the rate of 3d. for each 1 per cent. (calculated on the total weight of the basic slag) by which the quantity which will pass through such sieve as aforesaid is less than 80 per cent., but with an additional allowance at the rate of 9d. for each 1 per cent. (calculated as aforesaid) by which the quantity which will pass through such sieve is less than 75 per cent. The invoice to be given to purchasers as required by Clause 6 (c) of the above Order shall state in every case the percentage of the total weight of basic slag delivered which will pass through a sieve containing 10,000 apertures to the square inch.

For ground basic slag packed in special bags for carriage by sea an extra charge at the rate of 2s. 6d. per ton may be made.

FOURTH SCHEDULE.

Limits of Error referred to in Clauses 5 and 6 of the above Order.

<i>Fertiliser.</i>	<i>Contents, of which Percentage is to be stated on Invoice.</i>	<i>Limit of Error (calculated on the Total Weight of the Fertiliser).</i>
Superphosphate ..	Phosphate rendered soluble in water (calculated in terms of tri-basic phosphate of lime).	1 per cent.
Sulphate of ammonia ..	Ammonia (NH ₃)	25 per cent.
Ground basic slag ..	Total phosphate (calculated in terms of tri-basic phosphate of lime).	2 „

FIFTH SCHEDULE.

Scheme for Equalising Costs of Distribution of Superphosphate, Sulphate of Ammonia and Ground Basic Slag.

1. Each maker or producer of superphosphate, sulphate of ammonia or ground basic slag (hereinafter called "the maker") shall open with the Minister of Munitions or any other Government Department nominated by him for this purpose (hereinafter called "the Government") an account entitled "Delivery Charges on Fertilisers."

2. The Government shall be debited in such account with the costs of carriage incurred by the maker in delivering superphosphate, sulphate of ammonia or ground basic slag of his own manufacture sold by him at any time on or after the date on which the above Order takes effect for delivery between the 1st June, 1918, and the 31st May, 1919 (or such other date as may hereafter be fixed by the Minister), and actually delivered between those dates. Provided that except as otherwise expressly authorised by or under the authority of the Government from time to time, either generally or in the case of any particular sale on delivery by the maker :—

(a) The costs of carriage to be debited to the Government in the said account shall be the actual costs incurred by the maker, after deducting all rebates, discounts and allowances whatsoever.

(b) Nothing shall be debited to the Government in the said account in respect of costs of carriage on (i.) sales for delivery as mentioned in paragraphs

(b) and (c) of Clause 2 of the above Order, or (ii.) sales of any of the four classes specified in Clause 7 of the above Order.

(c) Only costs of carriage by rail or water shall be debited to the Government in the said account, and nothing shall be debited in respect of costs of loading or of cartage, whether from maker's works to railway station or wharf for putting on rail, barge, or ship, or at any other point of transit, except as otherwise expressly below mentioned.

(d) The costs which may be debited to the Government shall include :—

(i.) Demurrage incurred on railway wagons and vessels, if due to causes not within the control of the maker or the consignee ;

(ii.) In the case of carriage by water, insurance and shipping charges actually incurred, and also dock dues, if any ;

(iii.) In the case of transport partly by rail and partly by water, for which a through rate is not obtainable, any costs of cartage from rail to ship, or from ship to rail, and of putting on board or on rail at point of transfer ;

(iv.) In the case of sales for export to the Channel Islands or the Isle of Man, the costs of putting on board at port of shipment.

(e) The cheapest available route by rail or water must be adopted for all consignments, and in default the maker may not debit the Government with any extra costs of carriage incurred.

(f) No sales shall be made by the maker for delivery by rail or water in contravention of any general or special instructions or directions which may from time to time be given by or under the authority of the Government, or of any of the terms or conditions of the licence under which the same is made, and should any such sales be made, no costs of carriage incurred in delivering the fertiliser may be debited to the Government in the said account.

(g) In cases where superphosphate, sulphate of ammonia, or ground basic slag is consigned by the maker to his own local store for subsequent delivery or distribution :—

(i.) The cost of carriage by rail or water between the works and the store may be debited to the Government, such debit to be made when the fertiliser has been sold and delivered.

(ii.) Where such store has been approved by the Government for the supply by such maker of superphosphate, sulphate of ammonia and ground basic slag, or any one or more of such fertilisers, to any particular district (but not otherwise), any further costs of carriage by rail or water incurred by the maker in delivering superphosphate, sulphate of ammonia, and/or ground basic slag (as the case may be) from such store to purchasers or consumers within such district, may be debited to the Government ; and in addition, where the fertiliser is delivered into such store on or before the 31st December, 1918, the Government may also be debited with a further sum of 5s. per ton (in the case of superphosphate and sulphate of ammonia) and 2s. per ton (in the case of ground basic slag) to cover the cost of putting the fertiliser into and out of store, and

(iii.) Where such store has been specially approved by the Government for this purpose (either generally or as regards one or two only of the said three fertilisers) there may also be debited to the Government any costs (not chargeable to the purchaser under paragraphs (d) and (f) of Clause 2 of the above Order) of cartage or haulage of the superphosphate, sulphate of ammonia, and/or basic slag (as the case may be) into such store from the nearest or other approved railway station or wharf, provided that the same is delivered into such store on or before the 31st December, 1918.

(h) In the case of sales of ground basic slag for delivery in Ireland, nothing may be debited to the Government in the said account in respect of any costs of transport from port of arrival in Ireland to place of delivery.

3. The Government shall be credited in the said account with the sum of 12s. 6d. in respect of each ton of superphosphate, sulphate of ammonia, or basic slag, of the maker's manufacture, sold by him, on or at any time after the date on which the above Order takes effect, for delivery as mentioned in paragraphs (a), (d), (e) or (f) of Clause 2 of the above Order between the 1st June, 1918, and the 31st May, 1919 (or such other date as may hereafter be fixed by the Minister), and actually delivered between those dates, such credit to be made from time to time as and when the fertiliser is delivered. Provided that nothing shall be credited to the Government in respect of sales of any of the four classes specified in Clause 7 of the above Order.

4. The said account shall be balanced as on the 31st July, 1918, and the last day of each second calendar month thereafter, ending with the 31st May, 1919, or such other date as aforesaid; and any balance shown by any such two-monthly account to be due, either from the Government to the maker or from the maker to the Government, shall be paid within twenty-eight days after the same is ascertained, or otherwise as may be arranged.

5. The maker shall render to the Government an account for each two-monthly period aforesaid, in such form and containing such particulars as the Government may require, and shall produce to the Government's representatives, and, if so required, forward to them, together with each two-monthly account, the proper vouchers or certificates for all charges debited to the Government in such account. The maker shall keep (so far as practicable in separate books) true and accurate accounts and records of all costs of carriage incurred and paid by the maker in delivering superphosphate, sulphate of ammonia or basic slag, and shall, whenever required, submit his books and all relevant documents for examination by the Government's representatives.

NOTICE.—By arrangement with the Board of Agriculture and Fisheries, the Board of Agriculture for Scotland, and the Department of Agriculture and Technical Instruction for Ireland, the Minister of Munitions has (until further notice) delegated to those Departments, jointly, the carrying out of the scheme for equalising costs of distribution of superphosphate, sulphate of ammonia, and ground basic slag, set out in the Fifth Schedule to the above Order, and has nominated those Departments, jointly, as the Government Department which is to exercise all powers, authorities and discretions reserved to the Minister by the said Schedule, and with which the accounts referred to in the said Schedule are to be opened and kept, and also as the Government Department, by or under the authority of which licences under paragraphs (b), (c), or (d) of Clause 9 of the above Order (relating to sales and consignments of superphosphate and ground basic slag, and of sulphate of ammonia to be used for fertilising purposes) are to be issued. All communications and applications in connection with the said scheme for equalising costs of distribution (including applications for licences under Clause 9, paragraphs (b), (c), and (d) of the above Order) should, until further notice from those Departments, be addressed to Food Production Department, Board of Agriculture and Fisheries, 72, Victoria Street, S.W. 1.

All other applications in reference to the above Order (including applications for licences under Clause 9 (a)) should be addressed to the Director of Acid Supplies, Ministry of Munitions of War, Explosives Supply Department, Storey's Gate, Westminster, S.W. 1.

THE following Notice was issued by the Food Production Department of the Board in April :—

**Warning as to
Flue Dust.**

Farmers are warned against confusing boiler flue dusts and destructor dusts with blast-furnace flue dust. The former are in the main worthless as manures, and contain only about 0.5 per cent. of nitrogen and less than 1 per cent. of potash. Blast-furnace flue dust is a special material obtained from the flues of certain blast-furnaces and may contain from about 3 to 13 per cent. of potash. It is procurable from the agents approved by the Food Production Department for the sale of fertilisers, and a list of such approved agents may be obtained on application to the Food Production Department, 72, Victoria Street, London, S.W. 1.

THE following Letter (No. 21/Sr), dated the 2nd April, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Army Stable Manure.

DEAR SIR,—This Department has been in communication with the War Office with regard to the supply of army stable manure to allotment holders and farmers, and an Order of the Army Council was issued on the 10th ultimo drawing the attention of Officers in Command of Remount Camps to the great importance of the maximum effort being put forward, particularly during the next few weeks, to dispose of manure, utilising all the available transport which can be set apart for the work.

In drawing your attention to this Order I am to say that it is most desirable that your Committee should inform themselves as to the distribution of manure at Remount Depots in your county, and that they should draw the attention of allotment holders and agriculturists in the neighbourhood of such Depots to the available supply, with a view to seeing that as much as possible is taken away with all possible speed. It should, of course, be borne in mind that the need of transport for Army purposes must come first, and consequently allotment holders and farmers have no right to expect that manure shall be conveyed to their allotments or farms. Consumers must as far as possible supply their own transport.

In most instances a considerable supply of manure is being disposed of by the Military Authorities in the manner desired, but it may be that in some camps no definite demand on the part of growers has arisen.

In this connection I am to point out that by the Army Order allotment holders and kindred societies may be given preferential treatment to the extent that, after the first ton (which may be given free), only 6d. per ton need be charged at the dump (exclusive of delivery).

This Department will be glad to receive a report from your Committee at an early date upon the position with regard to such Remount Camps as may be situated in your county.

Yours faithfully,
(Signed) LAWRENCE WEAVER,
Director of Supplies.

AN Order (No. 372), dated 27th March, 1918, has been made by the Food Controller containing the following main provision :—

No person shall directly or indirectly sell
The Meat Retail Prices or offer or expose for sale or buy or offer to
(England and Wales) buy in England or Wales any meat by retail
Order No. 2, 1918. at prices exceeding the maximum prices
provide by or in pursuance of this Order.

The uniform scale of maximum retail prices for meat set out in the First and Second Schedules to this Order are not here printed. Copies of the Order may be obtained from H.M. Stationery Office, price 1d. net, including postage.

AN Order (No. 410), dated 10th April, 1918, has been made by the Food Controller to the effect that :—

1. General Prohibition Against Feeding The Horses (Rationing) Cereal Foodstuffs to Horses.—No person shall feed any horse or permit any horse to be fed with cereal foodstuffs except as provided in this Order, or under the authority of the Food Controller.

2. Horses Excluded from the Operation of this Order.—This Order shall not apply to horses falling within the classes mentioned in the First Schedule.

3. Limited Rations to Certain Horses—(a) Horses falling within the classes mentioned in the Second and Third Schedules may not on any day be fed with more than the quantity of cereal foodstuffs prescribed for such horses.

(b) The maximum quantity of cereal foodstuffs which may be fed on any one day is prescribed in the Schedules in terms of oats, but maize, beans, peas, or bran may be used in lieu of oats, and if so used they shall be deemed for the purpose of this Order to be the equivalent of oats in the following proportions :—

7½ lb. Maize	10 lb. oats.
9 „ Beans	10 „
9 „ Peas	10 „
12 „ Dried brewer's grains	10 „
13 „ Bran	10 „

No other cereal foodstuffs may be used.

4. Prohibition as Regards Certain Horses.—Horses falling within the classes mentioned in the Fourth Schedule may not be fed with any cereal foodstuffs.

5. Hay, Straw, etc.—No restriction is placed by this Order on the use of hay, straw or roots for the feeding of any horse.

6. Records.—Any person or persons in possession of a horse or horses falling within the classes mentioned in the Second and Third Schedules shall keep records of the number and classes of horses kept, in sufficient detail to show (1) the total maximum rations authorised by this Order, (2) the description and quantities of the foodstuffs fed to such horses per week, and (3) the description and quantities of all cereal foodstuffs purchased ; and such records shall at all reasonable times be open to the inspection of an officer of police or any person authorised by the Food Controller.

7. Interpretation.—For the purpose of this Order : “ Horse ” shall include mare, gelding, colt, filly, pony and mule. “ Cereal foodstuffs ” shall include all grains and beans and peas and products thereof.

Note.—This Order came into force on the 15th April, 1918, and revokes the Horses (Rationing) Order, No. 2, 1917.*

SCHEDULE I.

Horses excluded from the operation of this Order :—

- (a) Horses in the possession of the Army Council or the Admiralty, or exclusively used for the purposes of the Army Council or the Admiralty.
- (b) Horses maintained and used exclusively for agricultural purposes.
- (c) Stallions used exclusively for stud purposes.

* See this *Journal*, October, 1917, p. 780.

SCHEDULE II.

Horses solely or mainly used for trade or business purposes to be rationed :—

Class of Horse.	Maximum Daily Ration in Terms of Oats.	
	When in Hard and Continuous Work.	When not in Hard and Continuous Work.
(a) Heavy dray and cart horses, and trotting vanners.	14 lb.	10 lb.
(b) Light draught horses, and light trotting vanners.	12 „	8 „
(c) Other light horses and cobs ..	9 „	6 „
(d) Ponies 14 hands and under ..	5 „	3 „

NOTE.—(1) *The jobbing out of horses is not in itself a trade or business purpose within the meaning of this Order.*

(2) *Pit horses and ponies working in the pits or at the pit mouth may be given 4 lb. extra per day.*

(3) *Horses regularly engaged in work at a slow pace not involving heavy loads and allowing of frequent intervals of standing should be regarded as not in hard and continuous work.*

SCHEDULE III.

Horses not used for trade or business purposes to be rationed :—

Class of Horse.	Maximum Daily Ration in Terms of Oats.
(a) Brood mares	7 lb.
(b) Weaned foals	6 „
(c) Yearlings—	
1st January to 31st May	6 „
1st June to 31st August	3 „
1st September to 31st December	6 „
(d) Racehorses registered with the Controller of Horse Transport, 7, Whitehall Gardens, S.W. 1., for the purposes of the limited racing scheme	13 „

SCHEDULE IV.

Horses not to receive any cereal-foodstuffs :—

Horses not falling within any of the classes mentioned in Schedules I., II., and III., including :—

- Racehorses other than those specified in Schedule III.
- Carriage horses, hunters, hacks, char-a-banc horses, polo ponies, including all horses let out on hire for these purposes, and horses used in entertainments.
- Horses mainly used for other than business or trade purposes, including all horses let out on hire for other than these purposes.

NOTE.—Correspondence with respect to this Order should be addressed to the Controller of Horse Transport, 7, Whitehall Gardens, S.W. 1.

THE following Notice was issued by the Food Production Department of the Board early in May :—

Growing Maize for Fodder.

In the southern and south-eastern counties where, comparatively speaking, the climate is mild, the rainfall low, and periods of drought are frequent, no forage crop will better repay attention at the present time than maize. It does well in some parts of Cheshire ; but, as a rule, it is not to be depended upon north of the English Midlands. Easily cultivated it is suited to a variety of soils, and will produce a large bulk—20 tons and upwards per acre—of succulent material suitable for supplementary grass in early autumn, or, if made into silage, for replacing part of the winter root-ration. Resembling grass in general composition and feeding properties, maize is much relished by all classes of farm stock ; and it is especially valuable for dairy cows, encouraging a large flow of milk.

Seed at the rate of about 2 bush. per acre may be sown from the middle of May to the middle of June. The Supplies Division of the Food Production Department has made arrangements with the Royal Commission on Wheat for the disposal of a quantity of No. 2 Flat White South African Maize for sowing this season. The maize is being placed on sale through selected agents and the preliminary announcement has already brought in a brisk demand. Farmers interested should apply at once to the Food Production Department, 72, Victoria Street, S.W. 1, from whom full particulars can be obtained as to the nearest source of supply, the price, method of cultivation, etc.

Food both for man and beast is being derived from unexpected sources since war compelled us to take stock of our possible reserves.

**Fodder Substitutes :
Investigation of
Unused Resources.**

Useful food for poultry and pigs is being successfully prepared from household and slaughter-house waste ; but so far as the feeding of cattle and sheep is concerned, there has been little change in pre-war methods except a compulsory reversion to a more extensive use of roots and other farm crops to make up for the deficiency in cake and grain. There are three or four materials obtainable in considerable quantities at present going to waste which might possibly yield suitable food for different kinds of stock. A correspondent of the Ministry of Food draws attention to the fact that among the unused resources into which investigation is desirable are seaweed and the rhizomes and fronds of bracken.

Information with regard to the properties of these materials as feeding stuffs is still incomplete, although there are records of all their use as stock-food, and even as human food. It is, therefore, possible that experience may bring to light certain objections to the use of these substances which are not immediately apparent.

Value of Bracken.—In the utilisation of bracken as food there are two separate propositions which require to be considered : (1) the young fronds, (2) the rhizomes below ground which are at their best during winter and early spring. The fronds in their young and tender state have been used as food for stock, and even when they are fully grown in late summer and autumn have been given to cattle. But the evidence is that if cattle eat them at that stage in quantities and over considerable

periods outbreaks of poisoning occur. The poisonous properties only appear to develop in the later period of growth.*

Analysis shows that the rhizome is free from deleterious constituents, and expert opinion is that weight for weight it should be about half way in food value between mangolds and potatoes. If this estimate is correct, bracken rhizomes, which on fully-stocked land may amount to 12-16 tons per acre, should form a valuable addition, ground into meal, to winter fodder supplies. Further, the value of the rhizomes forms an incentive for the clearance of land which might otherwise continue to be waste, though our correspondent goes so far as to suggest that it may be more profitable to harvest the bracken regularly than to put the land under grass. It is important that experiments into the utility of the rhizomes as a feeding stuff should be made at once, as in another month they will have passed much of their reserve of food into the young fronds.

Dried Seaweed.—Seaweed has been fed to stock for generations in the crofting districts of the West Coast and the Islands, and in some places the cattle and sheep come down on the beach at low tide to feed on the seaweed. Dried and powdered seaweed fodder has been tried on a limited scale commercially, and although seaweed is not rich in nitrogenous content, and contains too high a proportion of alkali salts to be suitable for feeding alone, the industry appears to have a considerable future before it. In France, experiments have been made in removing a portion of the soluble ash for potash, and the resulting fodder has been fed to cavalry horses. If the French experiments prove successful and it is found possible to obtain two separate products from the seaweed, potash and fodder, there may be considerable commercial possibilities in the preparation of seaweed. By the present process of obtaining kelp only the potash is secured.

In the first instance, attention should be paid especially to those varieties which the cattle are found to select for themselves, and then to other varieties. At the present moment farmers who have been in the habit of using seaweed would render great service by communicating the results of their experience to the Agricultural Adviser of the Ministry of Food. The Germans are making extensive use of heather as fodder, and are said to be importing largely for that purpose. There, again, there is need for experiment and the pooling of experience. (*National Food Journal*, 24th April, 1918.)

THE proper use of the abundant supply of milk in spring and early summer is a matter of primary importance under war conditions.

Conditions are much more favourable in this country than in other parts of Europe. Nearly everywhere it has been found necessary to ration milk; and the Central Powers have, in many districts, found it impossible to meet even the priority claims of infants, invalids, nursing mothers, and children under six. Only skim milk is available for the general population, and that only in the smallest quantities. Sweden, and even

* See, however, this *Journal* for March last, p. 1446, where a Note on Bracken Poisoning appeared.

Switzerland, deprived of feeding stuffs by the blockade, have been compelled to institute a drastic control of milk supplies. Even in this country we cannot be assured against a possible shortage of milk, milk substitutes, and dairy produce in general next winter. It is, therefore, essential that producers should consider the most profitable use, from the national point of view, of available surplus milk. The first consideration is to secure an adequate and continuous supply, if possible, of fresh whole milk for those members of the community to whom milk is a vital necessity, *i.e.*, infants, young children, nursing and expectant mothers and invalids, whose claims are recognised by the Milk (Priority) Order of the Ministry of Food.

Generally speaking, the most economical use of milk is its consumption as fresh whole milk; but after the reasonable requirements of the community in this respect—and these must in no case be exceeded—have been met, there will be a surplus during the next few months. Moreover, there are farms so situated that there is no market for the product as liquid milk, and it is necessary for the producer to decide on the best use to which he can put his milk.

Roughly speaking, the milk not sold to consumers in the raw state is used for—

1. Conversion into dried or condensed milk which can be held in reserve for the winter when liquid milk is scarce.
2. Cheese-making.
3. Butter-making.
4. Feeding to stock.

In dried and condensed milk all the nutritive properties of the milk are retained, and evidence goes to prove that from the physiological standpoint dried milk is, with the proper addition to the diet of fresh fruit juice, an excellent substitute for fresh liquid milk; indeed, it is often found to be more easily digested by delicate children. The dried product possesses a certain advantage over condensed milk, since the latter, when once the tin is opened, offers a rich medium for the growth of organisms which may be introduced in unsanitary surroundings. There are certain difficulties, still unsurmounted, in preserving full cream dried milk which will keep for a long period, but half cream dried milk has excellent keeping qualities in addition to its other merits, and is possibly the most useful of all milk products. Both the condensation and drying of milk are factory processes, and cannot be carried out on a domestic basis. They are not, therefore, practicable outlets for small surpluses on remote farms where facilities for collection are not available.

Importance of Cheese.—Cheese has the next claim on the producer of milk. It is compact, durable, easily marketable, and contains fully two-thirds of the nutriment of the milk. The only important ingredient left in the whey is the sugar of the milk. Cheese-making can be successfully carried out with simple appliances on the farm, and even small surpluses of milk can be utilised in this way. Information on the methods suited to particular localities can be had from the County Council Education Authority, and the Board of Agriculture provide special leaflets on the question.* There is comparatively little waste of food material in cheese-making if the whey is fed to young stock. When

* Special Leaflet No. 75.—*The Manufacture of Cheese in Co-operative Dairies.*

" " " 78.—*The Profitable Utilisation of Surplus Milk.*

a calf reaches the age of three weeks milk can be gradually replaced by a mixture of whey and meal.

The third alternative is the making of butter. In butter, however, only about one-half of the food contents of the milk are retained. Butter-making is, therefore, uneconomical unless full use is made of the skim milk, which retains the muscle and bone-building ingredients. Where there is no sale for skim milk it might be made into skim milk cheese, though the market for cheeses of this kind has not hitherto been uniformly good.* There is a large demand for skim milk in other food preparations, and the Ministry of Food now have under consideration the different claims of the various industries concerned.

The advantages of cheese-making as compared with butter-making have been summed up by the Board of Agriculture as follows :—

1. It gives direct to the human consumer a greater proportion and a greater variety of the food materials contained in the milk ;
2. It is usually more remunerative, and is likely to remain so in view of the rapidly increasing competition of margarine with butter ;
3. It gives a more durable product capable of prolonged storage ; and
4. The accompanying whey, though less nutritious than skim or separated milk, can still be used satisfactorily for the purposes of calf-rearing or pig-feeding.

It should be unnecessary at this stage to remind farmers that the feeding of milk to stock for the production of veal or pork is the most wasteful of all the uses to which it can be put. So little human food is produced in this way in proportion to the milk consumed that the practice cannot be too strongly condemned even in normal times. As stated earlier in this article, it is possible to begin to replace the feeding of whole milk to calves at the age of three weeks only.

In order, then, to secure a steady supply of milk for direct human consumption throughout the year, it is desirable to encourage the manufacture of preserved forms of milk, especially of dried milk. The second economy is to secure that all surplus milk that cannot be made into condensed and dried milk should, as far as possible, be made into cheese. A reduction in the manufacture of butter in favour of cheese is highly desirable, but where butter is the only possible means of utilising surplus milk no effort should be spared to conserve as much as possible of the separated or skim milk for human consumption. (*National Food Journal*, 24th April, 1918.)

AN Order (No. 480), dated 27th April, 1918, has been made by the Food Controller to the effect that :—

<p>Order Continuing Temporarily the Cream Order, 1917.</p>	<p>The Food Controller hereby orders that the Cream Order, 1917†, shall continue in force until further notice, and that Clause 8 (b) of the Order shall be revoked.</p>
---	--

* An article on Skim Milk Cheese appeared in this *Journal*, May, 1917, p. 175.

† See this *Journal*, December, 1917, p. 1030.

AN Order (No. 401), dated the 5th April, 1918, has been made by the Food Controller amending the Grain (Prices) Order, 1917,* as follows:—

1. Clause 5 of the Principal Order is hereby
Order Amending revoked as on the 8th April, 1918, and the
the Grain (Prices) following Clause substituted:—
Order, 1917. “(5) On the occasion of the purchase of

any of the grains mentioned from any person who is a recognised dealer in grain and who is not the producer of the grain sold, the following provisions shall have effect:—

(i.) Where the purchase is made by a flour miller buying for the purpose of his mill, or is a purchase of barley made by any person, the maximum price shall be ascertained by adding 1s. per qr. to the price otherwise applicable according to the foregoing provisions of this Order.

(ii.) Where a purchase is a purchase of grain other than barley, and is made otherwise than by a flour miller buying for the purpose of his mill, the maximum price shall be ascertained by adding 2s. per qr. to the price otherwise applicable according to the foregoing provisions of this Order, provided that where the total quantity of a particular kind of grain purchased by one buyer from one seller does not in any period of seven consecutive days including the day of sale exceed 15 sacks, the maximum price in respect of each qr. so purchased shall be ascertained by adding 4s. per qr. to the price otherwise applicable according to the foregoing provision of this Order, and where such total quantity does not in that period amount to one sack, the maximum price in respect of each qr. so purchased shall be ascertained by adding 8s. per qr. to the price otherwise applicable according to the foregoing provisions of this Order.”

2. Nothing in this Order shall affect any contract made before the 11th April, 1918.

AN Order (No. 477), dated 24th April, 1918, has been made by the Food Controller to the following effect:—

An Order Revoking from the 1st May, 1918, the Wheat (Seed)
the Wheat (Seed) Order, 1918,† shall be revoked, but without
Order, 1918. prejudice to any proceedings in respect of any contravention thereof.

THE following Order (No. 459), dated 20th April, 1918, has been issued as a Royal Proclamation, under Section 3 of the Military Service (No. 2) Act, 1918 (8 Geo. 5, c. 5) withdrawing certain Certificates of Exemption from Military Service.

A Proclamation
Withdrawing Certain
Certificates of
Exemption from
Military Service.

Whereas by Sub-section (1) of Section 3 of the Military Service (No. 2) Act, 1918, it is provided that His Majesty may, by Proclamation declaring that a national emergency has arisen, direct that any certificates of exemption, other than certificates

* See this *Journal*, September, 1917, p. 673.

† See this *Journal*, February, 1918, p. 1299.

expressed to be granted or renewed solely on the ground specified in paragraph (c) or on the ground specified in paragraph (d) of Sub-section (1) of Section 2 of the Military Service Act, 1916, granted or renewed to any class or body of men specified in the Proclamation, or to men of any class or description so specified shall, as from the date specified in the Proclamation cease to have effect, and all certificates to which the Proclamation applies shall as from that date cease to be in force :

And whereas by Sub-section (2) of Section 3 of the Military Service (No. 2) Act, 1918, it is provided that while any such Proclamation remains in operation no application shall, except in so far as the Proclamation provides for the making of applications in any special cases, be entertained for the grant or renewal of the certificates mentioned in that Sub-section.

And whereas a national emergency has arisen :

Now, therefore, We, by and with the advice of Our Privy Council, in pursuance of the said Act and all other powers enabling Us in that behalf, do hereby direct that, as from the Twenty-fourth day of April, 1918, the certificates of exemption from military service specified in the First Schedule to this Our Royal Proclamation shall cease to have effect :

And in pursuance of the powers aforesaid We do hereby further direct that, notwithstanding that this Our Royal Proclamation is in operation, applications for certificates of exemption may be made in the special cases and subject to the provisions specified in the Second Schedule hereto.

FIRST SCHEDULE.

All certificates of exemption granted or renewed to men born in the years 1895, 1896, 1897, 1898, and 1899, exclusive of :—

(1) Certificates held by men who pursuant to their last authorised medical examination are at the date of this Proclamation :—

- (a) In Medical Category C 2, B 3, or C 3 or in Grade 3, or
- (b) In Medical Category B 1, B 2, B 3, C 1, C 2, C 3, or in Grade 2 or Grade 3 if in their case they are at the date of this Proclamation whole-time employed on a farm in farm work and are duly registered pursuant to the National Registration Acts, 1915 and 1918, as being occupied on agricultural work.

(2) Certificates granted or renewed on grounds of employment by Colliery Recruiting Courts to persons employed in or about coal mines.

(3) Certificates granted or renewed on grounds of employment by Port Labour Committees, or the London Shipowners and Transport Workers Military Service Committee to men who at the date of this Proclamation are pursuant to their last authorised medical examination in a medical grade or category other than Grade 1 or Category A.

(4) Certificates granted or renewed to persons who at the date of this Proclamation are duly qualified medical practitioners.

(5) Certificates expressed to be granted or renewed solely on the ground specified in paragraph (c) or on the ground specified in paragraph (d) of Sub-section (1) of Section 2 of the Military Service Act, 1916, that is to say, on the grounds of ill-health or infirmity or of a conscientious objection to the undertaking of combatant service.

SECOND SCHEDULE.

A. Application may be made to an Appeal Tribunal for the grant or renewal of a certificate of exemption solely on the ground specified

in paragraph (a) of Sub-section (1) of Section 2 of the Military Service Act, 1916, in respect of a man who has established to the satisfaction of the County Agricultural Executive Committee in England or Wales, or the Board of Agriculture for Scotland in Scotland, that he is a highly skilled agricultural worker, whole-time employed on a farm in farm work, and that he is irreplaceable and essential to the cultivation of the farm, provided that the application is lodged in accordance with the Regulations for Tribunals not later than the 15th day of May, 1918.

B. Application may be made to a Tribunal for the grant or renewal of a certificate of exemption :—

- (i) Solely on the ground specified in paragraph (b) of Sub-section (1) of Section two of the Military Service Act, 1916, in respect of a man who establishes to the satisfaction of the Tribunal that he is the last surviving son of a widow, of whom at least one son has died as a result of wounds received in, or sickness contracted by, service with Our Armed Forces during the present War ; or
- (ii) Solely on the ground specified in paragraph (d) of Sub-section (1) of Section two of the Military Service Act, 1916, in respect of a man whose certificate was expressed to be granted or renewed on such ground in addition to a ground specified in paragraphs (a) or (b) of that Sub-section ;

provided that such application is lodged, in accordance with the Regulations for Tribunals, not later than the Eighth day of May, 1918.

Given at Our Court at Buckingham Palace, this Twentieth day of April, in the year of our Lord One thousand nine hundred and eighteen, and in the Eighth year of Our Reign.

God Save the King.

EXPLANATORY NOTES.

Note 1.—This Proclamation operates to withdraw only certificates of exemption granted by Tribunals and by Government Departments under Section 2 of the Military Service Act, 1916. It does not affect protection certificates issued under the Schedule of Protected Occupation M.M. 130 (Revised), namely, Forms 3476A, 3476B and 3476 W.M.V., to men employed on Admiralty, War Office or Munitions work, or protection certificates issued to men employed by Railway Companies.

Note 2.—Certificates of exemption to which this Proclamation applies cease to be in force on the 24th April, 1918. The holder of such a certificate must forthwith transmit the certificate, together with a notification that it has ceased to be in force, to the Local Office of the Ministry of National Service for the area in which the holder of the certificate is registered under the National Registration Acts, 1915 and 1918. If any man fails without reasonable cause or excuse to do so he is guilty of an offence under the Military Service (No. 2) Act, 1918.

THE following Circular (No. R. 181), dated 23rd April, 1918, has been issued by the Local Government Board :—

<p>Local Government Board Circular Letter : Proclamation With- drawing Certificates of Exemption.</p>	<p>SIR,—I am desired by Mr. Hayes Fisher to enclose a copy of a Proclamation* which has been issued withdrawing certificates of exemption held by men born in the years, 1895, 1896, 1897, 1898, and 1899, with certain exceptions. Provision is made in the Proclamation that applications for exemption may be made by certain classes of men coming within the terms of the Proclamation.</p>
--	--

* See above.

The classes are specified in the Second Schedule to the Proclamation and are—on the ground of occupation, agricultural workers who comply with certain conditions; on the ground of serious hardship, the only sons of widows who have lost one or more sons in the present war; on the ground of conscientious objection, men who hold certificates granted on that ground as well as on the ground of occupation or of hardship.

The only men in agriculture whose certificates are withdrawn by the Proclamation are men in Medical Grade 1 or Category A, or men who have not been medically graded or classified.

As regards other classes, the Proclamation withdraws the certificates of men in Medical Grades 1 or 2 or in Categories A, B 1, B 2, or C 1, or men who have not been medically graded or classified.

2. It is imperative that any applications made under the Proclamation shall be dealt with immediately. Regulations have therefore been prepared (copies are enclosed)* under which any application in respect of a man coming within the Second Schedule of the Proclamation shall be made direct to the appropriate Appeal Tribunal, and shall be dealt with by that Tribunal in the same manner as applications made direct to them.

Applications concerning the sons of widows or on the ground of conscientious objection have to be delivered not later than the 8th May next, and concerning agricultural workers not later than the 15th May. Mr. Hayes Fisher hopes that the Appeal Tribunals will make arrangements for deciding any such applications within fourteen days of their receipt. He will be glad to receive not later than the 8th June a statement respecting the cases in the form which is enclosed.*

3. It will be observed from the Second Schedule that, in the case of agricultural workers, an application may be made only in respect of a man who establishes to the satisfaction of the County Agricultural Executive Committee that he is a highly skilled agricultural worker, whole-time employed on a farm in farm work, and is irreplaceable and essential to the cultivation of the farm.

An application of this kind will therefore not be valid and should not be entertained unless it is accompanied by a statement or certificate from the Agricultural Executive Committee that they are satisfied that the conditions are fulfilled.

Directions to the Agricultural Executive Committees will be issued by the Board of Agriculture.

As to the interpretation of "whole-time on a farm in farm work," reference may be made to the following quotation from the Memorandum R. 144, of the 24th July last†:—

"Employment 'whole-time on a farm on farm work' is intended to cover the production of essential food supplies, and therefore includes the work of men whole-time employed on a market garden exclusively in production of food of a kind and quantity of national importance. It is not to include work on a poultry farm or on a market garden for the production of flowers or fruit.

"Farm work covers the employment of men in agriculture as thatchers or as drivers of engines or motor tractors (including tractor ploughmen); but these men, as others, must comply with the conditions stated above . . ."

Mr. Hayes Fisher suggests that, as regards the agricultural cases, the Tribunal (a small committee or committees of three to five members will be best) should first go through the cases with the National Service

* Not here printed.

† See this *Journal*, August, 1917, p. 569.

Representative and the Agricultural Representative. It will probably be found that in some cases exemption may be given, with the concurrence of the National Service Representative, without a hearing. In those cases which it is found necessary to hear, notice of hearing should be issued forthwith. No application can be refused without a hearing.

4. In dealing with these cases it must be borne in mind that the general rule which the Government have adopted is that the men of the ages and medical standards covered by the Proclamation are to join the Colours; that an exception to this rule is justified only if it can be shown that special conditions prevail; and that, therefore, it must be shown, in the case of an agricultural worker, that it is clearly in the national interest that he should be allowed to continue in his civil employment, taking due account of all other possible measures for carrying on the work which is done by him, and, in the case of the only son of a widow, that there would be such serious hardship if the man were called to the Colours as to justify an exception to the general rule.

I am, etc.,
(Signed) H. C. MONRO,
Secretary.

THE following Circular Letter (No. 66/L1), dated 26th April, 1918, was addressed to Agricultural Executive Committees by the Food Production Department of the Board:—

**Military Service:
Royal Proclamation
of the 20th April
Withdrawing
Exemptions.**

SIR,—1. By Royal Proclamation issued 20th April, 1918, all certificates of exemption or protection granted or reviewed to men employed in agriculture, who are medically classified Grade 1 or Category "A," or who have not yet been medically graded or classified, will cease to have effect as from the 29th April, 1918, provided such men were born in the years 1895, 1896, 1897, 1898, or 1899.

2. Men of all other medical categories or grades, who are at the date of the Proclamation whole-time employed on a farm on farm work, and are duly registered under the National Registration Acts 1915 and 1918 as being employed on agricultural work, are not affected.

3. Applications for certificates of exemption in special cases may be made in respect of men referred to in paragraph (1) of this Memorandum, provided any man, by or on behalf of whom such application is made, has established to the satisfaction of the County Agricultural Executive Committee concerned, that he is *a highly skilled agricultural worker, whole-time employed on a farm on farm work and that he is irreplaceable and essential to the cultivation of the farm.* An application in respect of any such man or men must be lodged *with the Appeal Tribunal* in accordance with the Regulations for the time being in force, *not later than the 15th day of May, 1918.*

An application made on the ground referred to in this paragraph will only be considered by the Appeal Tribunal of the area in which the man is employed, if it is accompanied by a declaration from the County Agricultural Executive Committee for the area in which the man is employed, that they are satisfied that the conditions specified

above are complied with. Applications will therefore be submitted in the first instance direct to the Executive Committee concerned.

4. Agricultural Executive Committees will observe that very onerous duties have been placed upon them under this Proclamation which will require their immediate attention and necessitate frequent sittings in view of the short period of time allowed for the making of appeals. This matter should be treated as the most urgent and important work to be performed by Agricultural Executive Committees at the moment, and if necessary extra clerical assistance should be temporarily engaged at once to cope with it.

5. The Department desire that the following procedure should be adopted in every county :—

- (a) If possible, the names of the men falling within the terms of the Proclamation should be obtained at once by your Committee from the Regional Representative of the National Service Department, whose names and addresses are given in Appendix A.*
- (b) A specimen form (F.P. 250 L.1)* is enclosed to be used by every farmer making application for leave to appeal for the exemption of any man coming within the terms of the Proclamation, which it will be noted include men in Grade 1 or Category "A," or *men not medically examined*, who fall within the age limits named. A somewhat similar form (F.P. 251 L. 1) is enclosed* for use in the case of every market gardener.
- (c) It is essential that these forms should be sent to all farmers in the county who, as a result of the information obtained under paragraph (b), or from inquiries received, are known to have in their employment men falling within the terms of the Proclamation.
- (d) Committees should arrange special meetings during the next 14 days to consider applications received from employers for leave to appeal for exemption for the men concerned. The general decision of the Cabinet is that the men of the ages and medical standards covered by the Proclamation are to join the Colours. An exception to this rule is to be made only if it can be shown that special conditions prevail, and therefore it must be proved, in the case of an agricultural worker, that it is in the national interest that he should be allowed to continue in his civil employment, taking due account of all other possible measures for carrying on the work which is being done by him. Agricultural Executive Committees must recognise their responsibility in this matter, and only sanction appeals to the Tribunal in cases which clearly satisfy the conditions laid down in paragraph 3 above.
- (e) In cases in which the Committee are satisfied that the man concerned is a highly skilled agricultural worker whole-time employed on the holding in farm work, that he cannot be replaced, and that he is essential to the cultivation of the holding, a declaration signed by the Chairman should be issued in the form attached (F.P. 249 L.1).* The form should be sent to the employer and a copy to the Appeal Tribunal of the area in which the man is employed ; at the same time the employer should be notified of the address of the Appeal Tribunal with whom the application should be lodged.
- (f) As to the interpretation of the term "employment whole-time on a farm on farm work," attention is drawn to the following quotation from the Memorandum R. 144 of 24th July, 1917* :—"Employment 'whole-time on a farm on farm work' is intended to cover the production of essential food supplies, and therefore includes the work of men whole-time employed on a market garden exclusively in the production of food of a kind and quantity of national importance. It is not to include work on a poultry farm or on a market garden for the production of flowers or fruit. Farm work covers the employment of men in agriculture as thatchers or as drivers of engines or motor tractors (including tractor ploughmen) ; but these men, as others, must comply with the conditions stated above if vouchers are to be issued in respect of them." This definition remains in force.

* Not here printed.

- (g) Instructions are being issued by the Local Government Board to Tribunals which provide that a Committee of 3 or 5 members of the Tribunal may review the cases referred to it, with the Representatives of the Ministry of National Service and Board of Agriculture. It is expected that in a number of cases exemption may be given with the concurrence of the National Service Representative without a hearing, but in cases where a hearing is essential, notice will be given by the authorities concerned. No application can be refused without a hearing. The Tribunals have been requested by the Local Government Board to make arrangements for deciding applications referred to them within 14 days of their receipt.
- (h) Committees should post to the Food Production Department, each Wednesday and Saturday, particulars of the cases dealt with during the period on the form (F.P. 252 L.1)*, of which a specimen is attached.

All appeals must be lodged with the Tribunal before 15th May, therefore it is important that applications should be received and dealt with by your Committee by 11th May at latest.

Owing to the very urgent circumstances Committees are authorised to arrange for the necessary printing to be done locally.

I am, etc.,

(Signed)

A. LEE,

Director-General of Food Production.

THE following Memorandum (No. 59/L1), dated 15th April, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Substitution in
Agricultural Cases.**

Inquiries have been addressed to the Department from time to time by Agricultural Executive Committees as regards the action they should take in the cases of men fit for general service for whom suitable substitutes could be provided. The question has recently been further under consideration, and in view of the urgent need of the Army for men fit for general service an arrangement has been arrived at with the Ministry of National Service whereby it should be possible to release a number of men without depleting the manpower of any farm.

The arrangement is outlined in the enclosed copy of a Circular Letter* issued by the Ministry of National Service, which indicates generally the procedure that is most likely to secure the release of men, while safeguarding the interests of food production.

It will be observed that the powers of the Agricultural Executive Committees under this Department's Memorandum F.P. 83 are in no way affected by the present arrangement, as their consent has still to be obtained before any man, who was on 1st June, 1917, whole-time employed on a farm on farm work of national importance and is still so employed, can be posted for service with the Colours or called up for medical examination or re-examination. Agricultural Executive Committees may, however, be asked to indicate the individual men whom they would be prepared to release for military service upon the provision of substitutes, and they will therefore have ample opportunity of satisfying themselves that the substitutes offered are suitable, and consequently that the amount of skilled labour on farms is safeguarded. Further-

* Not here printed.

more, it is clearly indicated that the men serving in Agricultural Companies will not be offered in substitution, so that labour from this source will continue to be available.

In view of the present military situation, it is hoped that the Agricultural Executive Committees will co-operate cordially with the local representatives of the Ministry of National Service in the working of this scheme, which has for its object the securing of more men for the Army without depleting the amount of skilled labour available for farm work.

THE following Memorandum (No. 54/L2), dated the 3rd April, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Soldier Labour.

Copies of Army Council Instruction 322* of 1918, relating to the employment of soldiers on agricultural work, are enclosed for the information of Agricultural Executive Committees. It will be observed from paragraph 1 that, as from the date provided in that paragraph, farmers will be required to provide board and lodging for soldiers employed in agriculture and to pay for their services at the local "living-in" rate, with a minimum of 10s. per week.

The application form (F.P. 71) for soldier labour is being amended, and copies will be forwarded to all Committees as soon as possible. In the meantime the existing copies of this form should be used, a slip being added explaining the alteration as regards board and lodging.

THE following Notice was issued in April by the Food Production Department of the Board :—

**Appeal for
Village Forewomen.**

Women with agricultural experience are urgently required by the Food Production Department, to act as "Village Forewomen" to lead and arrange the work of gangs of women on the land during the coming season. They will be paid a minimum wage of 25s. a week, and must enrol in the Women's Land Army for six months and be prepared to work wherever they are required throughout England and Wales. Applications for forms of enrolment should be sent in writing to the Women's Branch, Food Production Department, 72, Victoria Street, S.W. 1.

THE Board of Agriculture announce that an arrangement has been made with the Ministry of National Service and the War Office for a definite number of 30,000 Grade 1 men to be made available from agriculture for military service not later than 30th June.

**Agriculture and
Recruiting.**

It is hoped that the large majority of these men will be recruited under the Proclamation of 19th April, 1918, calling up men born in the years 1895-1899, but, if the full number of men is not obtained under this Proclamation, it will be necessary to obtain the remainder from men up to 31 years of age.

It is expected that additional labour, including a large number of prisoners of war, will be made available for agriculture to take the place of the men urgently required for immediate military service.

* Not here printed.

THE following Notice was issued by the Agricultural Wages Board on 13th May :—

**District Wages
Committees.**

District Wages Committees have now been established for each of the 39 areas into which England and Wales was divided for this purpose under the provisions of the Corn Production Act. The District Committees are now generally engaged in formulating their recommendations to the Agricultural Wages Board. The reports of their proceedings in the Press appear in some cases to have given rise to the belief that the decisions of the Committees at once become operative. This is not the case. Any recommendation of a District Committee has to be sent up for consideration to the Agricultural Wages Board, who alone have power, under the Act, to fix minimum rates of wages. When the Board have come to a decision on a recommendation from a District Committee they are bound to give formal notice of any rate which they propose to fix, and to allow one month, during which objections to their proposals may be made, before an Order is made legally fixing the rate. The Board, however, have recommended that employers should, in all cases, agree with their workers that any rate which may be so fixed shall be retrospective as from the end of March last.

**Agricultural Wages
Board: New Minimum
Rates of Wages
for Male Workmen
in Norfolk.**

THE Agricultural Wages Board (England and Wales) give notice that they have fixed the following minimum rates of wages for male workmen of 18 years of age and over employed in agriculture for time work in the area comprising the administrative county of Norfolk and the county boroughs of Norwich and

Great Yarmouth, that is to say :—

(1) The wages payable for employment in summer (as hereinafter defined) of male workmen in agriculture of 18 years of age and over shall be not less than wages at the minimum rate of 30s. for 54 hours (exclusive of meal times),

(2) The wages payable for employment in winter (as hereinafter defined) of male workmen in agriculture of 18 years of age and over shall be not less than wages at the minimum rate of 30s. for 48 hours (exclusive of meal times).

(3) The above minimum rates shall apply to all male workmen of 18 years of age and upwards who are wholly or partly employed in agriculture within the meaning of Section 17 (1) of the Corn Production Act, 1917, in the above-mentioned area during such time as they are so employed.

(4) For the purpose of the above minimum rates employment in summer shall be deemed to be employment during the period commencing on the first Monday in March and terminating on the last Sunday in October; and employment in winter shall be deemed to be employment during the rest of the year.

(5) The above minimum rates shall come into operation on the 20th day of May, 1918.

THE following Memorandum (No. 48/C2), dated 2nd May, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Rook Shooting.

Complaints are made as to the excessive number of rooks, and it is suggested that the services of rifle clubs might be enlisted with a view to using .22 miniature

rifle cartridges, of which there are large stocks available, for the purpose of shooting the birds.

The Department ask that the Agricultural Executive Committees will urge the owners of rookeries to invite members of the local rifle clubs to undertake such shooting.

Supplies of '22 cartridges can be obtained on application to the Rabbits and Game Advisory Committee, Ministry of Food, 14, Upper Grosvenor Street, London, W. 1.

The wholesale destruction of rooks, however, is not advocated, having regard to the undoubted advantage which farmers derive from a limited number of the birds.

THE Board desire to give notice that the particulars of the Routes of the Stallions to which premiums have been awarded by the Board for the service season 1918, together with the names and addresses of the owners of the stallions, and of the members of the Stallion Committees which have been appointed to supervise the service arrangements, will not be published in this *Journal*. Copies of a list of the names and routes of these stallions may be obtained on application to the Board's Offices, 4, The Sanctuary, Westminster, London, S.W. 1.

SINCE the date of the List given on p. 1052 of the *Journal* for December, 1917, the following Leaflets have been issued in the Permanent Series:—

Leaflets in 1918. No. 312.—*Blossom Wilt of Apple Trees.*
 ,, 319.—*Apple Capsids.*

The following Food Production Leaflets have been issued:—

- F.P. No. 18.—*Seed Testing for Farmers at the Official Seed Testing Station.*
 ,, 21.—*Wart Disease of Potatoes: Report on the Immunity Trials at Ormskirk in 1915-16-17.*
 ,, 23.—*Blast Furnace Flue-Dust as a Potash Manure.*
 ,, 25.—*Economy in the Feeding of Dairy Cows.*
 ,, 26.—*Economy in the Use of Seed Grain.*
 ,, 28.—*Leaflet on Potato Wart Disease, specially prepared for Children who cultivate School Gardens and for Amateurs in Gardening.*
 ,, 29.—*Suggestions to Farmers in the Breaking up and Cropping of Grass Land.*
 ,, 32.—*Spring and Summer Spraying of Fruit Trees in Small Plantations.*
 ,, 33.—*Fertilisers for Farm Crops in 1918.*
 ,, 34.—*Canning of Fruit and Vegetables.*
 ,, 35.—*Varieties of Oats for Spring Sowing.*
 ,, 36.—*War-time Allotments.*
 ,, 37.—*Soiling Crops for Dairy Cows.*
 ,, 38.—*Wheat Growing.*
 ,, 39.—*The Control of Pests of Fruit Trees in Gardens and Small Orchards.*
 ,, 40.—*The Stock-carrying Capacity of Grass and Tillage Lands.*
 ,, 42.—*The Cultivation of Buckwheat.*
 ,, 43.—*Practical Hints on Potato Spraying.*

In addition, the information in the following Permanent Leaflets has been revised and brought up to date :—

- No. 23.—*Potato Disease.*
- „ 46.—*Stem Eelworm.* (This has been re-written.)
- „ 56.—*Apple Canker.* (This has been re-written.)
(This was previously entitled "*Canker Fungus.*")
- „ 65.—*Small Ermine Moth.*
- „ 70.—*Treatment of Neglected Orchards.*
- „ 80.—*Use of Artificial Manures.*
- „ 93.—*Farmyard Manure.*
- „ 112.—*Weeds and their Suppression.*
- „ 142.—*Calf Rearing.* (This has been re-written.)
- „ 170.—*The Use of Lime in Agriculture.*
- „ 173.—*Potato Growing.*
- „ 193.—*Dry Rot of Potatoes.* (This has been re-written.)
- „ 226.—*Broom-rape.*
- „ 231.—*Cheese-making for Small Holders.*
- „ 254.—*The Use of Seaweed as Manure.*
- „ 255.—*The Workmen's Compensation Act, 1906.*
- „ 264.—*The Cultivation of Onions.*
- „ 277.—*Tuberculosis in Farm Stock.*
- „ 285.—*Bacon Curing on the Farm.*
- „ 296.—*Potato Growing in Allotments and Small Gardens.*
- „ 297.—*Seed Testing.*

The following Leaflets, formerly issued in the series of Special Leaflets, have been added to the Permanent Series :—

- No. 315.—*Suggestions to Allotment Holders for General Cropping during the Spring and Summer Months.* (Formerly Special Leaflet No. 26.)
- „ 316.—*Sorghum as Fodder.* (Formerly Special Leaflet No. 53.)
- „ 317.—*The Rearing of Chickens.* (Formerly Special Leaflet No. 54.)
- „ 318.—*Economy in Using Potatoes.* (Formerly Special Leaflet No. 67.)
- „ 320.—*Manuring Cottage Gardens and Allotments.* (Formerly Special Leaflet No. 56.)

The following Food Production Leaflets have been revised and brought up to date :—

- F.P. No. 2.—*Credit for Farmers.*
- „ 5.—*Notes on Breaking up Grass Land.* (This has been re-written.)
- „ 11.—*Hints on Purchasing Seed Potatoes.*
- „ 19.—*Pig Feeding in War Time.* (This has been re-written.)

The following Leaflet, formerly in the series of Special Leaflets, has been transferred to the Food Production Series :—

- F.P. No. 41.—*The Making of Fruit Pulp.* (Formerly Special Leaflet No. 31.)

The following Leaflet, which had been withdrawn from circulation, has been re-written and re-issued :—

- No. 114.—*The Feeding of Poultry.*

The following Leaflets have been withdrawn from circulation :—

- No. 92.—*Bunt and Smut.*
- „ 120.—*Peach Leaf-Curl.*
- „ 217.—*The Provision of Allotments.* (This is replaced by F.P. Leaflet No. 36.)
- „ 247.—*Shot-hole Fungus.*
- „ 256.—*A Disease of Narcissus Bulbs.*

The following Special Leaflets have been withdrawn from circulation :—

- No. 17.—*Supplies of Pit Timber.*
- „ 21.—*The Manufacture of Charcoal.*
- „ 49.—*The Selection of Wheats for Spring Sowing.*

THE Meteorological Office will, as in past years, but subject to certain restrictions, supply forecasts of weather by telegraph to persons desirous of receiving them, upon payment of a registration fee of 1s. and the cost of the telegrams, computed at 9d. per day. The supply of forecasts will continue until 30th

September. The forecasts are drawn up each week-day at 4.30 p.m., and refer to the probable weather during the 15 hours from 6.0 a.m. to 9.0 p.m. on the next day. The addition of a "further outlook" and the issue of notifications in connection with spells of settled weather are suspended during the War.

Applications for the forecasts should be sent to the Director, Meteorological Office, South Kensington, London, S.W. 7, with a cheque or postal order payable to the Meteorological Committee, to cover the cost of the telegrams for the period, which should not be less than 6 consecutive days, during which the forecasts are to be sent.

**Maximum Retail and
Wholesale Prices:
A Correction.**

The Board desire to correct a printer's error which appears on p. 126 of this *Journal* for last month. The particulars of the home-grown grain of the 1917 crop given thereon should be included under a side heading "**Crain**," which word was omitted when the *Journal* was in the Press.

Birmingham.—Andrew Huntchback, Baschurch, Salop, on sales of watered milk, £90.

**Prosecutions of
Farmers, etc., under
Statutory Rules and
Orders.**

Bridgnorth.—John Lucas, farmer, on sales of seed potatoes (and sales otherwise than by weight), £11 19s. 6d., including costs.
Darlington.—Fines amounting, with costs, to £100 were imposed upon James Dent, farmer and butcher, Goosepool, for having slaughtered sheep and cows contrary to Orders and failed to keep records.

Finsbury.—Edward R. Morris, Paul Street, on sales of milk diluted 31 per cent., £50.

Greenwich.—The West London Dairy Company, on sales of watered milk at Deptford, £40, with £5 15s. 6d. costs. The depot staff was said, in defence, to have been since "cleared out."

Hendon.—Thomas Whiting, Dollis Farm, Mill Hill, on a sale of watered milk, £25.

Leytonstone.—Alfred Cleall, roundsman, on sales of milk short measure, £10 or 61 days' imprisonment.

Stratford.—Henry Payne, Beachcroft Road, employed by the Upton Park Co-operative Society, for sales of short-measure milk, £10 or 61 days' imprisonment.

Woburn.—John Edwin Andrews, Charlton Cross Farm, Toddington, was summoned for contravening the Wheat, Rye and Rice (Restrictions) Order, 1917, by permitting a stack of wheat to be damaged by rats.

Of 60 or 70 qr. 5 or 6 bush. had been destroyed, and witnesses computed there must have been from eighty to hundred rats in the stack. The defendant was fined £50.

Woolwich.—Victor Johnson, Footscray Road, New Eltham, and Harry Furber, Southend Farm, on sales of milk, £10 and £25 respectively, the latter with 5 guineas costs. (*National Food Journal*, 24th April, and 8th May, 1918.)

NOTICE OF BOOKS.

The Wheat Problem (3rd Edition). Sir William Crookes (London: Longmans, Green & Co., 1917, 3s. 6d. net).—This work is based on remarks made in the Presidential Address to the British Association for the Advancement of Science, delivered by Sir William Crookes at Bristol in 1898. A full report of the Address, which at the time attracted such widespread attention, appears in this edition, and is followed by a chapter on the Recent Developments of the Wheat Problem, the statements made in the original Address being reviewed in the light of subsequent events, especially in regard to the War, while some of the criticisms to which his Address has been subjected are examined.

The contention of the author in 1898 was that the wheat-producing soil of the world was totally unequal to the strain which was being put upon it, and that, unless the aid of science was called in to increase the acreage yield of wheat, dearth, and possibly famine, was a possible contingency in the near future. Wheat is pre-eminently a crop demanding large quantities of nitrogen, and as this constituent is mainly of atmospheric origin, it needs to be "fixed" before it can be properly utilised as a plant food. The future problem, therefore, is to devise methods of fixation which will enable the nitrogen supply of the world to be conserved and utilised to the fullest possible extent with a view to a more intensive cultivation of the wheat-growing areas.

In his Presidential Address of 1898, as reprinted in this book, the author first gives a statistical survey of the position of the principal wheat-producing countries in the world, and after showing the urgent necessity for obtaining an increased acreage yield by the application of nitrogenous fertilisers, owing to the gradual appropriation of all the available land for wheat-growing purposes, states the case for nitrogen fixation. In the following chapter a more general review of the present position is made, and the methods of nitrogen fixation described more in detail.

An introduction to the volume is contributed by Lord Rhondda, who briefly mentions a few instances of what science has done and is capable of doing for agriculture, especially in regard to making the country more self-supporting in the matter of foodstuffs. A chapter on the Future Wheat Supplies, by Sir Henry Rew, K.C.B., dealing with the world's supply of cereals during the War, the fluctuations which have occurred in the different countries during this period, and the past position and the outlook of England in the production of cereals, concludes the volume.

Note.—The question of Nitrogen Fixation is also dealt with in a pamphlet on "The Nitrogen Problem and the Work of the Nitrogen Products Committee," issued by the Ministry of Munitions, and obtainable from the Stationery Office, price 2d., excluding postage (see this *Journal*, January, 1918, p. 1254).

MISCELLANEOUS NOTES.

THE *International Crop Report and Agricultural Statistics* for April, 1918, issued by the International Institute of Agriculture, contains the following estimates of the production of cereal crops in the Southern Hemisphere :—**Wheat.**—**Notes on Crop Prospects and Live Stock Abroad.** In Argentina, Uruguay, Union of South Africa, Australia, and New Zealand the production in 1917-18 is estimated to amount to 46,134,000 qr. against 29,683,000 qr. in 1916-17, or an increase of 55·4 per cent., the area sown showing an increase of 2·0 per cent. **Oats.**—The total production in Argentina and New Zealand is placed at 8,795,000 qr. in 1917-18, or an increase of 123·1 per cent. compared with 1916-17, when it amounted to 3,942,000 qr., while the area sown was greater by 19·3 per cent.

Sowing of Winter Cereals in the Northern Hemisphere.—The areas estimated to have been sown with winter *wheat* in 1917-18, compared with the areas sown during the corresponding period of 1916-17, expressed as percentages, are as follows :—Denmark 102, Spain 98, France 107, England and Wales 115, Scotland 122, Luxemburg 105, Canada 96, United States 105, British India 110, Japan 118, Tunis 113 ; with *rye* :—Denmark 118, Spain 108, France 96, England and Wales 103, Luxemburg 95, United States 145 ; with *barley* :—Spain 108, France 92, England and Wales 100, Japan 99, Tunis 111 ; with *oats* :—Spain 123, France 106, England and Wales 100, Tunis 120.

France.—According to the official report, the weather during March was generally fine and dry, and although snow fell in many districts during the early part of the month, the conditions were on the whole favourable for the growing crops and spring sowing. The appearance of the autumn sown crops continues satisfactory, and spring sowing is in some districts well advanced. Potato planting is nearly completed, but meadows have, on the whole, suffered somewhat from drought. (*London Grain, Seed and Oil Reporter*, 13th April, 1918).

The Ministry of Agriculture on the 18th April issued an estimate of the crop conditions on the 1st April, as follows (figures for 1st April, 1917, in brackets) :—Winter wheat, 73 (54) ; winter barley, 72 (56) ; winter oats, 70 (52) ; and rye, 74 (62). (80 = good, 60 = fairly good, 50 = passable.) (*Broomhall's Corn Trade News*, 19th April, 1918.)

United States.—According to a report issued on 8th May by the statistician of the Department of Agriculture, the average condition of winter wheat and rye in the United States on 1st May was estimated as follows :—Wheat, 86·4 per cent., compared with 78·6 per cent. on 1st April, and 73·2 per cent. a year ago ; and rye, 85·8 per cent., compared with 85·8 on 1st April, and 88·8 a year ago. The area still under winter wheat is estimated at 36,392,000 acres (or 13·7 per cent. less than the area planted in the autumn), compared with 27,430,000 acres last year, and the yield is estimated at 572,500,000 bush., compared with 418,000,000 bush. last year. The estimated yield of rye is 82,600,000 bush. against 60,145,000 bush. last year. Of spring ploughing 77·5 per cent. and of spring planting 60·8 per cent. was completed by 1st May, as against 72·4 per cent. and 58·7 per cent. respectively last year. (*The London Grain, Seed and Oil Reporter*, 8th May, 1918.)

India.—According to a special official forecast the yield of wheat in India for the season 1917-18 is estimated at 47,959,000 qr. as against the final forecast of 47,404,000 qr. for 1916-17 and 39,750,000 qr. for 1915-16. (*London Grain, Seed and Oil Reporter*, 30th April, 1918.)

Australia.—According to the reports of observers of the Commonwealth Meteorology Department the weather conditions during January varied from actual drought in some parts to serious floods in others. The wheat crop is disappointing, and the fruit yield is also light and has suffered in quality from excess of moisture. Grass and water have, with little exception, been sufficient and in many places abundant; stock is for the most part in very good condition, and the dairying industry most flourishing.

South Africa.—According to a report issued on the 15th February, excessive rains have fallen over a great part of the maize-growing area of the Union, and ploughing operations have been greatly hindered. Although the area under this crop was greater by 5 per cent. than a year ago, the condition of the crop at the end of January indicated a yield 18 per cent. below normal, owing to the excessive rains and attacks of rust and insects; and should there be no improvement during the ensuing months of the season the crop will probably not exceed 3,500,000 qr. compared with 4,000,000 qr. last year, and 5,000,000 qr. the previous year. (*London Grain, Seed and Oil Reporter*, 18th April, 1918.)

Live Stock in Australia.—According to a return issued by the State Statistician, the numbers of live stock in New South Wales on the 30th June last was as follows (figures for June, 1916 in brackets) :—Horses, 733,828 (719,542); cattle, 2,765,767 (2,405,770); sheep, 36,179,730 (32,600,729); and pigs, 359,780 (281,158). (*The London Grain, Seed and Oil Reporter*, 23rd April, 1918.)

THE Crop Reporters of the Board, in commenting on agricultural conditions in England and Wales on the 1st May, state that spring sowing of corn has been practically completed

**Agricultural
Conditions in
England and Wales
on 1st May.**

under favourable conditions. Autumn wheat looks well and promising, though, owing to the cold weather, it has made but slow progress, and is in some places a little discoloured. Winter oats and beans are also quite satisfactory generally. The spring-sown crops are mostly coming up nicely, though oats are not in all cases so satisfactory; they, as well as the spring wheat, have been to some extent damaged by wireworm, which has been rather troublesome on newly-ploughed land. Warmer weather is needed to bring all the crops on, and in some districts rain is also required.

Potato planting has been nearly completed in the Fen districts; but a large area remains to be sown in Lancashire. Elsewhere the work is generally in full swing; it was in many parts interrupted by bad weather in the middle of the month. Generally the seed has been got in under very favourable conditions. Some damage to the earlies by frost is reported from the south-western counties.

Seeds are generally a good plant, though thin in the eastern counties; but the cold has allowed of very little growth during the

month. It is quite anticipated, however, that they will come on well with warmer weather, and under favourable conditions they should give a satisfactory yield.

Pastures are still mostly bare, and have not given much feed to the stock that have been turned out on to them. Like the clovers, they require warmth to bring them on. Live stock are generally healthy, but tend to be lean, as winter fodder is in many places finished, and grass is very backward.

Except in the latest districts lambing is practically over. The fall of lambs has been everywhere quite up to the average, and in many places over, while mortality, both among ewes and lambs, has been low, so that the season may be described as a good one. Hill flocks in the north have not done quite so well, as the weather was less favourable in their case.

The more skilled forms of labour are still very scarce, but with the assistance of soldiers, women, and prisoners of war, work is well advanced.

The following local summaries give further details regarding the agricultural labour in the different districts of England and Wales :—

Agricultural Labour in England and Wales during April. *Northumberland, Durham, Cumberland, and Westmorland.*—On the whole the labour position is fairly satisfactory; skilled men are scarce, but there are fair numbers of substitutes. A shortage of temporary labour

for potato planting is, however, being experienced in some parts of Durham.

Lancashire and Cheshire.—The supply of labour is very short, temporary labour being almost unobtainable.

Yorkshire.—In some districts there is sufficient labour, and nearly everywhere there is no great scarcity, as many women, soldiers and German prisoners are available. The scarcity of horsemen seems to be the chief difficulty.

Shropshire and Stafford.—The supply of labour, both skilled and casual, is very short, and soldier labour is scarcer than it was. With the help of women and prisoners of war, however, the work has been kept well in hand.

Derby, Nottingham, Leicester, and Rutland.—Labour, both skilled and casual, is still very deficient, but with the help of soldiers, women, and prisoners of war work has been kept well in hand.

Lincoln and Norfolk.—The supply of labour varies in different parts of the division. There is generally a shortage, but it does not appear to be serious, and work is well advanced.

Suffolk, Cambridge, and Huntingdon.—In most districts there is about sufficient labour, and nowhere does the supply seem very much deficient, although skilled workers are scarce. Women have been available for potato planting.

Bedford, Northampton, and Warwick.—The supply of labour is generally short, though in many places it is sufficient with the assistance of soldiers and women.

Buckingham, Oxford, and Berkshire.—Labour is generally deficient, but with the help of soldiers, women and prisoners of war, farmers are able to carry on. One district of Oxfordshire reports increased wages for skilled cattlemen.

Worcester, Hereford, and Gloucester.—The supply of labour is still deficient, but the employment of women, soldiers and boys eases the position.

Cornwall, Devon, and Somerset.—The supply of labour, especially skilled, is short.

Dorset, Wiltshire, and Hampshire.—Labour is still short, but with the favourable season the work has been done with the assistance of women, soldiers, and in some cases, German prisoners. Skilled horsemen are scarce.

Surrey, Kent, and Sussex.—Skilled labour is deficient, but the work is kept in hand by the help of soldiers and women. Wages are being increased in some places.

Essex, Hertford, and Middlesex.—Though the supply of labour is deficient, the situation does not appear serious. Soldiers and German prisoners have greatly helped the situation. Wages have gone up.

North Wales.—Labour is very scarce, especially skilled, but with the assistance of soldiers, women and children for potato planting, farmers have been able to carry on, and work has been kept well in hand.

Mid Wales.—Labour, especially skilled labour, is very scarce, and becoming more so as men are called up, but, with the advantage of good weather and the help of women and German prisoners, farmers have been able to get well forward with their work.

South Wales.—Labour is very scarce, but owing to the favourable weather work is well forward.

THE following statement shows that according to the information in the possession of the Board on 1st May, 1918, certain diseases of animals existed in the countries specified:—

**Prevalence of
Animal Diseases on
the Continent.**

Austria (on the 20th March).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Denmark (month of February).—Anthrax, Swine Erysipelas.

France (for the period 17th March—6th April).—Anthrax, Black-leg, Foot-and-Mouth Disease, Glanders, Rabies, Sheep-pox, Swine Erysipelas, Swine Fever.

Germany (for the period 15th—28th February).—Foot-and-Mouth Disease, Glanders and Farcy, Swine Fever.

Holland (month of February).—Anthrax, Foot-rot, Swine Erysipelas.

Hungary (on the 20th March).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Italy (for the period 1st—7th April).—Anthrax, Black-leg, Foot-and-Mouth Disease (2,396 outbreaks), Glanders, Rabies, Sheep-pox, Sheep-scab, Swine Fever.

Norway (month of March).—Anthrax, Black-leg.

Sweden (month of March).—Anthrax.

Switzerland (for the period 1st—7th April).—Black-leg, Foot-and-Mouth Disease, Swine Fever.

No further returns have been received in respect of the following countries: Belgium, Bulgaria, Montenegro, Rumania, Russia, Serbia, Spain.

THE JOURNAL

OF THE

BOARD OF AGRICULTURE

Vol. XXV. No. 3.

JUNE, 1918.

THE REARING OF CALVES IN THE SUMMER AND AUTUMN OF 1918.

ON many farms at the present time the rearing of calves is beset with exceptional difficulties owing, on the one hand, to the necessity—both from patriotic and economic motives—of restricting the use of milk for this purpose to the bare minimum, and, on the other hand, to the difficulty of obtaining adequate supplies of suitable feeding-stuffs with which to supplement this scanty allowance of milk. The difficulty is mainly limited to farms providing milk or dairy produce for human consumption, and, amongst these, varies according to the system of farming, being most acute on the milk-selling farm and least so on the butter-making farm. On the former, whole milk must be completely replaced by concentrated foods, whereas on the latter they are required only to supplement the supplies of separated milk available for rearing purposes. The cheese-making farm occupies an intermediate position, since, although whey is available, it has a lower feeding-value than separated milk and requires a correspondingly richer or more abundant supplement in the form of concentrated feeding-stuffs.

In dealing with calf-rearing under present conditions there are thus three separate cases to consider, according as separated milk or whey or neither is available.

Before proceeding to outline methods of rearing that are adapted to the requirements of the times, a word may first be said as to the possible feeding-stuffs that are likely to be available in reasonable quantity for the purpose. Of home-grown crops use can be made of oats, beans, peas and linseed. In the case of purchased foods the most suitable that are likely to be available are linseed cake, palm kernel cake, coconut cake and fish meal. Maize meal, gluten feed and locust

bean meal may also be added to the list, although supplies will probably be very short. Milling offals as now produced are not equal to the finer offals of pre-war days, but may be used to a limited extent.

Under the existing arrangements for the rationing of feeding-stuffs the allowance of concentrated food for calves is restricted to calves up to 6 months old, and is not likely to exceed $\frac{3}{4}$ lb. per day, or, roughly, $1\frac{1}{4}$ cwt. per calf. The way in which the use of this should be distributed over the period for which concentrated food is required will vary according to the time of calving and the quantity of milk, separated milk, or whey that can be allowed for the calf. Assuming that the use of concentrated food is spread over 24 weeks, the above amount represents an average of rather less than 1 lb. per day, which permits of an allowance of 1 lb. per day until the calf is 18 weeks old (assuming the first 2 weeks on whole-milk alone) and thereafter of $\frac{1}{2}$ lb. per day. Alternatively, the meal allowance might start with $\frac{1}{2}$ lb. per day at 2 weeks old, rising fortnightly by $\frac{1}{4}$ lb. to $1\frac{1}{2}$ lb. at 10 weeks old, and then decreasing fortnightly by $\frac{1}{4}$ lb. to $\frac{1}{2}$ lb. per day, this rate then being continued until the calf is 6 months old.

Economy in the Use of Whole Milk.—The extent to which whole milk is used for calf-rearing must be determined primarily by the possibilities of profit offered by its use in other directions, such as the production of butter or cheese or direct disposal of milk for human consumption. One gal. of milk of average quality contains about $1\frac{1}{4}$ lb. of actual food material, which is equal in feeding value to about $2\frac{1}{2}$ lb. of the best concentrated feeding stuffs (except linseed). The sale of milk even at 1s. per gal. thus means a realisation of nearly 10d. per lb. for the food material contained in it. Similarly, a price of 1s. 4d. per lb. for cheese or 2s. 6d. per lb. for butter is equivalent to a realisation of 13d. or 8d. per lb., respectively, for the foodstuff in the milk.* So long, therefore, as suitable feeding-stuffs can be obtained to replace it at a price of 2d. per lb. (= £18 13s. 4d. per ton) or thereabouts, which is, roughly, the current level of prices, there is obviously the strongest inducement to impose the narrowest limits upon the consumption of milk by calves where sale of milk or dairy produce is possible.

Experiments at Woburn and elsewhere have shown that it is possible to restrict the use of whole milk to the first two weeks of the calf's life, although it is more common to prolong

* It is assumed that 1 gal. of milk will give 1 lb. of cheese or $\frac{1}{2}$ lb. of butter.

it to the third or fourth week. No fixed rule can be laid down, since the rearer must be guided by the progress of the calf and the supplies of milk available. The rate at which the change from milk to other diet is made should vary according to the character of the latter. In substituting separated milk for whole milk the change may, if necessary, be effected in three or four days, but, in passing to a whey or water diet, the change should be spread over a period of one or two weeks.

The allowance of milk from the second or third day after calving is usually from 4 to 6 qt. per day, given in three meals. A similar bulk of separated milk, whey or water should be used when the change is made, increasing gradually, as the calf grows, up to a maximum of about $2\frac{1}{2}$ gal. per day. After about the sixth week the food can be given in two meals, morning and evening. From this time also a little good hay should be placed at the disposal of the calf and a little broken linseed cake placed in the feeding trough at midday.

Rearing with Separated Milk.—The essential difference between whole milk and separated milk is that the latter is almost entirely devoid of cream or butter-fat, hand-skimmed milk being intermediate between the two in this respect. In using separated milk, therefore, it is necessary to supplement it with a "cream equivalent" to make good the missing butter-fat. The simplest course would appear to be to add to the separated milk some cheaper fat or oil readily assimilated by the calf. This has been done in the past with considerable success by the use of cod-liver oil and other oils, but under present conditions both supply and cost of oils virtually preclude their use.

Recourse must be had, therefore, to the more ordinary concentrated feeding-stuffs. Certain of these, either alone or in mixtures, have been largely used with good results. Of the single feeding-stuffs the best results have been obtained with linseed and crushed oats.

Linseed possesses the special merits for this purpose of being rich in oil (30 to 40 per cent.) and of being easily converted into a porridge or gruel which is readily taken by the calf. For the same weight no other feeding-stuff provides as much nourishment. The import of linseed, however, is now controlled, and it is very unlikely that during the War any large quantity will be liberated for agricultural purposes, so that the dairy farmer with the necessary facilities will be well advised to grow a supply for his own use.

Before use the linseed should be boiled or ground. The latter is the simpler process, and can be readily effected in an ordinary steel grist-mill. For grinding with stones it will be advisable to add a small proportion of material such as maize, tail barley, or oats to prevent clogging of the mill by the pasty linseed.

For use the ground linseed should be scalded and stirred with boiling water at the rate of 1 qt. of the meal to 1 gal. of water. One pint of the porridge thus prepared added to 4 pt. of separated milk will suffice for a calf 4 to 5 weeks old. If the linseed be not ground it should be fed as a gruel prepared by boiling for 20 minutes with water at the rate of 3 gal. of water to 2 lb. of linseed, the latter being put in to soak overnight.

Linseed has a laxative tendency, and if this be too pronounced, it must be counteracted. Before the War an admixture of flour was commonly used for the purpose, but this is now inadmissible. Probably finely-ground maize meal or bean meal will serve the purpose.

The suitability of crushed oats for use along with separated milk has been demonstrated by experiments at Woburn and Kilmarnock and in Ireland.

In the Woburn experiments the calves were kept on whole milk until 3 or 4 weeks old, and towards the end of this period a handful of the crushed oats was mixed with the milk, and by the sixth week, when they were put entirely on to the separated milk, each calf was eating about 1 lb. per day along with $1\frac{1}{2}$ gal. of separated milk. After the calves were 12 weeks old the oats were given dry. Calves will soon take to oats in this form if the oats are put into the pail just before the milk is finished.

In the Kilmarnock and Irish experiments a similar procedure was adopted with equally favourable results. Good results were also obtained in both cases with maize meal, but this was scalded and fed along with the separated milk in the form of a porridge.

Linseed cake meal has also been frequently used along with separated milk with satisfactory results, although, being poorer in oil, it is not as nutritious as whole linseed. Very little experience with palm kernel cake and coconut cake has been recorded, but there is no obvious reason why they should not prove satisfactory either alone or in admixture with other better-known foods.

The following practice is reported to be giving good results. New milk is given for the first two weeks, then half new and

half separated milk for the next two weeks, and afterwards separated milk, hay and a little linseed cake. Soon this cake is mixed with coarse pollards and palm kernel cake, flavoured with a little treacle water and locust bean meal.

In using meals the standard aimed at should be to give roughly 1 lb. of meal per gal. of separated milk, since the mixture should then have approximately the same feeding value as the gallon of whole milk which it replaces. The limiting factor however, is usually the effect upon the digestive system of the calf, which needs to be carefully watched and the feeding regulated accordingly. Moreover, the present restricted supplies of feeding-stuffs will hardly admit of feeding on this scale.

Rearing with Whey.—Whey is less well adapted for calf-rearing than separated milk, since it lacks not only most of the fat but also most of the albuminoids—so important for growth—of the original milk. The albuminoids remaining in the whey can be recovered and used for calf-rearing by the following method, which is successfully practised on many cheese-making farms in Cheshire:—

“Directly the whey is run from the curd, it is put into a large copper, and then heated over a quick fire. The albumen coagulates, and, just before boiling point, rises to the top in flakes, known as ‘fleetings.’ These are skimmed off as they rise. The whey must on no account be allowed to boil, or the ‘fleetings’ will sink to the bottom. To assist them to form it is often helpful to add 2 or 3 qt. of cold whey. This also checks the bulk from boiling.

“The boiler must be thoroughly cleaned out each day after use, and for this purpose a soft brick or rubbing-stone is best.

“The calves are fed twice a day as follows:—

1st week	4	qt. milk per day.
2nd	“	“
3rd	“	—6 “ half milk and half ‘fleetings’ per day.
4th	“	—8 “ —2 qt. milk and 6 qt. ‘fleetings’ per day.
5th	“	—8 “ —1 qt. milk and 7 qt. ‘fleetings’ per day.
6th	“	—8 “ ‘fleetings’ per day.

“Milk is rarely given after the calves are 6 weeks old. As soon as possible a little soft meadow hay is given to the calves, and after about a week’s time a little bran as trough food. When the calves are 6 weeks old, and are getting no new milk, a little linseed cake and kibbled oats in equal proportions are added to the bran. Each calf is allowed about $\frac{1}{2}$ lb. of the mixture. This is gradually increased to about 1 lb. per calf per day. The calves are put out to pasture when they are finally weaned (about 5 months old), generally about the

second week in June. The quantity of 'fleetings' is gradually reduced, and in the last week only one feed per day is given. The weaning process extends over two weeks. If the weather is very wet or cold the calves are brought in for a few nights, and get a little corn and cake, otherwise they are left out at pasture for about three months, and are entirely dependent upon the grass."

Recent experiments (1916, 1917) at Kilmarnock have demonstrated that calves can be reared fairly satisfactorily on ordinary whey supplemented by meals. In these experiments palm kernel cake meal alone, a mixture of oatmeal (2 parts) and fish meal (1 part), and a mixture of fine thirds (2 parts) and fish meal (1 part) were tested separately along with whey. The mixtures were given in the form of porridge, but the palm kernel meal was fed dry. The replacement of the whole milk by whey began when the calves were 3 week old, and the change was spread over 3 weeks, *i.e.*, the calves were 6 weeks old before the whole milk was entirely withdrawn. By this time each calf was receiving about 1 gal. of whey and $\frac{1}{2}$ lb. of meal, and the consumption for the remainder of the experiment averaged about $1\frac{1}{2}$ gal. of whey and 1 lb. of meal per day. Hay was fed from the time the calves were 5 weeks old, and linseed cake introduced into the ration three weeks later, starting with a very small quantity and increasing up to an average of $\frac{3}{4}$ lb. daily. In each case the rate of growth was not much lower than that with other calves reared on separated milk and crushed oats, but was obtained far more cheaply. The cheapest rearing was effected in each year by the use of palm kernel meal.

Mr. Lawrence, of Newton Rigg, reports good results by using a whey porridge made from a mixture of linseed cake meal (4 parts), gluten meal (3 parts) and locust bean meal (2 parts). The mixture ($1\frac{1}{4}$ lb.) is scalded with 2 qt. of boiling water and mixed with $1\frac{1}{2}$ gal. of whey when serving.

Rearing with Meals Alone.—Where neither separated milk nor whey is available the rearing, after whole milk is withdrawn, must be carried on with meals alone. The feasibility of this mode of rearing has been demonstrated in various experiments, but, unfortunately, in most cases the "milk equivalent" meals used have included ingredients (*e.g.*, oatmeal, wheat-flour) which are not now available for the purpose. The general practice is to feed the meals in the form of gruel, but recent experiments have shown that meals can be satisfactorily fed in the dry form, whereby much time and labour can be saved.

The following meal mixtures have been used in this way with success at the Midland Agricultural and Dairy College:—

1. Linseed cake (finely natted)	4 parts.
Wheat germ meal	5 "
Dried yeast..	1 part.

The mixture, with a little salt added, was given at the rate of $\frac{1}{4}$ lb. per calf daily at the beginning, and it was increased gradually, as there was no difficulty in getting the calves to take it. During the transition period a little was given as a gruel in the milk—an excellent gruel being obtained simply by soaking in water 12 hours before feeding.

2. Linseed cake (finely natted)	4 parts.
Bean meal	5 "

This mixture, also with a little salt, was fed in the same quantity as the previous mixture and with equally satisfactory results.

The total quantity of new milk consumed by each calf was from 35 to 40 gal. ; the allowance of dry meal was gradually increased from $\frac{1}{4}$ lb. per calf per day, when 4 weeks old, to $2\frac{1}{4}$ lb. per day when 14 weeks old. Hay was given from the sixth week onwards. During the period of experimental feeding (11 weeks) the calves in both lots increased in live weight at the rate of fully 1 lb. per head per day and were equal to another lot reared on separated milk and crushed oats.

In experiments at the Royal Agricultural Society's farm at Woburn in 1915-16 different lots of calves were reared on crushed oats, palm kernel cake meal, crushed beans, and crushed maize respectively. In the following year crushed oats and palm kernel cake were again tested separately, and, in addition, trials were made with the following three mixtures: crushed oats and beans, crushed oats and palm kernel cake, maize and fish meal. In every case the calves were given whole milk only for the first fortnight, then during the third week changed to the meal and water diet, so that the consumption of milk was very small. The calves were allowed to have a little long hay as soon as they would take it, and at 8 weeks old began to receive a little linseed cake ($\frac{1}{4}$ lb.) in addition to the other food. At 5 or 6 weeks old a little hay chaff was mixed with the foods, as it was found that the calves then took their food better. With the exception of the maize, which was scalded, the foods were all given dry. Some difficulty was experienced in getting the calves to eat the palm kernel cake, and it is recommended that it should be given in kibbled form mixed with crushed oats. The amount of concentrated food

given was gradually raised up to 1 lb. or $1\frac{1}{4}$ lb. per calf per day. The results obtained in the 12-14 weeks' special feeding were as follows :—

	1915-16.		1916-17.	
	Gain per Calf per week. lb.	Cost per lb Gain in Live weight. d.	Gain per Calf per week. lb.	Cost per lb. Gain in Live weight. d.
Crushed oats and separated milk	6'58	4'71	—	—
Crushed oats, with water ..	3'73	2'74	2'75	5'15
Palm kernel cake ..	6'00	1'70	4'71	2'29
Beans ..	4'56	2'14	—	—
Maize ..	4'54	2'98	—	—
Crushed oats and beans, with water ..	—	—	6'07	2'79
Crushed oats and palm kernel cake, with water ..	—	—	7'33	2'29
Maize and fish meal, with water	—	—	7'35	2'41

A proprietary calf-meal was also tested each year and gave average weekly gains of 2'85 lb. and 5'32 lb. respectively.

It will be seen from the above table that the best results were obtained with the mixtures, and that of the single foods palm kernel cake gave the best and cheapest results, whilst oats alone proved rather disappointing.

Lawrence has obtained good results with a mixture of linseed cake (3 parts), middlings (1 part), and locust bean meal (1 part); and also with a mixture of palm kernel cake (6 parts), bean meal (4 parts), and locust bean meal (1 part). In each case the amount of the mixture fed ranged up to $2\frac{1}{2}$ or $2\frac{3}{4}$ lb. per head per day.

There are good reasons for believing that a mixture of foods will generally give better results than any single feeding-stuff, and the experiments quoted make it clear that reasonably good results can be expected from mixtures compounded from linseed, oil-cakes, fish meal, and maize or oats.

Further experiments under the auspices of the Board of Agriculture are at present in progress at Reading, in which the following mixtures are being fed along with whey :—

1. Linseed meal ..	3 parts.	4. Linseed meal ..	1 part.
Bean meal ..	3 "	Coconut cake meal	1 "
Fish meal ..	1 "	5. Linseed meal ..	3 "
2. Linseed meal ..	3 "	Linseed cake meal	2 "
Ground oats ..	3 "	6. Bean meal ..	5 "
Fish meal ..	1 "	Linseed cake meal	4 "
3. Linseed meal ..	2 "		
Fish meal ..	1 "		

In each case the meal mixture is fed at the rate of 1 lb. per gal. of whey, a small quantity ($\frac{1}{2}$ oz.) of precipitated bone-flour being also added. Actual results are not yet available, but up to the time of writing no trouble has been experienced with any of the mixtures, and the calves have made good progress.

In these days of restricted choice of feeding-stuffs calf-rearing must necessarily proceed largely upon experimental lines, and the nature of the feeding must be determined more by the available feeding-stuffs than by established practice. The results obtained may not be as good as have been customary in the past, but with reasonable care it should be possible to bring the calf satisfactorily through the critical period of rearing until it can maintain an adequate rate of growth on home-grown foods.

(This article is also issued in the form of Food Production Leaflet No. 14, copies of which may be obtained free on application.)

THE MANUFACTURE OF SMALL CHEESE WITH IMPROVISED APPARATUS.

MANY farmers and milk producers who are anxious to make cheese hesitate to make arrangements to do so because they fear that it may not be possible to obtain all the utensils which they consider are required. It is necessary, therefore, to consider how far it is possible to improvise and employ the ordinary utensils which are commonly possessed by the dairy farmer.

There are three articles which the prospective maker must obtain and for which no substitutes are possible. These are a thermometer, rennet, and cheese moulds. Other utensils found in the farm dairy may usually be made to serve the purpose of the cheese maker.

Cheese is usually made in a double-jacketed vat. In this vat the milk is renneted and allowed to coagulate. When coagulation is complete the curd is cut with special knives and heated to the proper temperature by admitting steam or hot water into the outer jacket. When in the right condition as regards acidity and dryness the whey is drawn off through the tap provided and the curd is allowed to acidify in the vat, or it is removed to a curd sink or cooler to complete the process of ripening. At the proper stage the curd is usually ground in a special mill, salted, placed in the cheese moulds and then put to press. Pressure of the cheese is necessary for several reasons. Firstly, it consolidates the curd, making the cheese firm and easily handled. Secondly, it is necessary to press a cheese to prevent the curd draining too much and rendering the cheese hard. It also stops to a great extent the further

development of acidity, which, if allowed to continue, would result in a hard, sour cheese having very little food value. Thirdly, it is necessary in order to form a close and impervious coat on a cheese, since mites and the maggots of flies enter and quickly destroy an unpressed cheese.

There are types of cheese which are unpressed, and these are of considerable size. For example, the Stilton is an unpressed cheese, but at the present time it is not advisable to make this class of cheese as it is really a luxury, while a great deal of skill and practice are required to ensure successful manufacture, the process being spread over a long period. The farmer who wishes to make cheese for his own consumption or for sale should elect to make a cheese of the Cheddar, Cheshire, or Derby type. These are best made of mixed morning's and evening's milk, and if the evening's milk is slightly sour, so much the better. A useful size of cheese is one of about 10 or 12 lb. in weight. Of course, almost any size of cheese less than 10 lb. can be made in the same mould or hoop, provided there is a sufficient number of wooden followers or blocks to enable pressure to be exerted on the cheese.

How to Make the Cheese.—A short description of the manufacture of the type of cheese which is most easily made under improvised conditions may be of value to the prospective maker.

As already stated, the cheese selected should be of the Cheddar, Cheshire, or Derby type, these being best made of mixed milks. The evening's milk should be placed in the dairy in ordinary setting pans or creamers and the cream allowed to rise. Next morning the cream should be removed and placed in a separate vessel on one side. All the skimmed milk should be poured into the vessel in which it is intended the cheese shall be made. As the warm milk comes in from the cowshed it should be added by passing it through a strainer along with the cream obtained from the evening's milk. This will mix in the cream and ensure that the whole is an even liquid.

Acidity and "Starters."—By the use of milk from two milkings the maker ensures the presence of a certain amount of acidity which is absolutely necessary if good cheeses are to be made and finished in reasonable time. The scientific cheese-maker uses a "starter" for the purpose of obtaining the required degree of acidity in milk. This starter contains pure cultures of the ferment which produces lactic acid. As, however, there is difficulty in getting suitable starters, and as the postal

rates have of late been raised, it rests with the cheese maker to provide his own starter.

If it is found that the milk works slowly and that there is delay in getting enough acid in the curd, the maker should set on one side a quart or so of freshly-drawn milk in a clean glass jar covered with a clean cloth. This should be allowed to stand in a moderate temperature till it gets sour, and in that condition it can be used as a starter to promote acidification in the milk, at the rate of 1 per cent. or one pint to each hundred pints of milk used. This starter should be strained and added to the bulk of the milk after the latter has been heated to renneting temperature. Generally, however, it is found that if the milk is set and skimmed in the ordinary way, there will be sufficient acidity in the mixed milk to ensure a satisfactory cheese.

The Cheese Vat.—The milk being to hand, the farmer who is without a cheese vat must consider how best to improvise. Any well-tinned vessel of sufficient capacity can be used, but a shallow vessel is better than a deep one.

The feeding or supply tank of a milk cooler or separator answers admirably, since, as it has a tap, the whey is more easily drawn off. An enamelled bath will also serve. A clean wooden tub, such as the body of an end-over-end butter churn, can be used, in which to coagulate the milk, and is excellent if made of oak, as the whey does not penetrate into the pores of the wood. Small quantities of milk are best set up in wooden vessels, as the heat is thus retained for a longer period. Galvanized vessels should not be used, however, as the acid in the whey forms a poisonous compound with the zinc used in the coating process.

Temperature.—The milk being in the setting vessel, the temperature will need to be raised to the proper degree. When making up small quantities of milk the setting temperature should be higher than would be the case with large vats of milk. A temperature of about 86° F. will give good results.

The milk can be heated either by placing a portion of it in a clean pail in a copper of hot water or a pail of hot water can be stood in the milk, the milk being well stirred till the proper temperature is obtained (see Leaflet No. 231 for instructions in heating milk and whey). The milk being raised to the correct temperature, it will be necessary to ascertain if it is sufficiently acid. This is done by adding 1 dram of rennet to 4 oz. of milk at 84° F. in a cup or glass, and stirring in quickly for 10 seconds. If at the end of 20 seconds

the curd "catches," *i.e.*, exhibits a slightly granular form on the finger, then the milk is ready for the rennet. If not, it must be allowed to stand till the maker considers that it is time to add the rennet. In no case should the maker attempt to make cheese from perfectly fresh milk. The use of fresh milk delays the process of cheese-making; it usually results in the production of a cheese of inferior quality and flavour, the cheese does not drain properly, and in the course of a few days such cheeses swell and afterwards leak in the curing room and deteriorate rapidly. If no sour milk is available and the milk is too sweet, then a little fresh clean-flavoured butter-milk can be used with advantage.

Renneting.—Rennet should be used at the rate of one dram to 3 gal. of milk. If no proper measure is at hand then the rennet may be measured out at the rate of 20 drops for each gal. of milk used. One ordinary teaspoonful of rennet extract is sufficient to coagulate 3 gal. of milk. The rennet should be mixed with a little clean water before it is added to the milk, and it should be stirred in briskly for a minute or so after addition, and the milk should be stirred occasionally, on the surface only, for not longer than 10 minutes. This stirring prevents the cream rising and results in a more uniform cheese. When the milk has stood for about 45 minutes it should be ready to cut.

Cutting the Curd.—If, on the insertion of a finger, the curd feels firm and splits clean it is ready for cutting. If no proper cheese knives are available the curd can be cut with a large carving knife or a ham knife. It should be cut into $\frac{1}{2}$ -in. squares as gently as possible and then diagonally. It should then be broken up very gently into "cubes" with the hand or with a skimming dish, and the sides of the vessel should be cleaned down. The curd should now remain untouched for 15 minutes or so, and then be stirred gently for a few minutes. The curd at this stage should be of the size of haricot beans, and the whey should be green and not milky.

If the maker wishes to produce a Cheshire type of cheese the temperature of the contents of the cheese vat should gradually be raised to 92° F. If a Cheddar cheese is required then the whole will need to be raised to 100° or 102° F.

If the cheese tub has no water compartment the temperature must be raised by removal of a portion of the whey, heating it in a pail in a copper or other vessel, and returning it to the cheese tub. To get off the whey the proper course to follow is to allow the curd to settle for a few minutes

and then to insert a cheese cloth. This cloth is spread over the vat and depressed till it reaches the curd and a pool of whey has collected. The cloth is used to separate the curd from the whey, so that some of the whey can be ladled out into a pail. This should be heated to not more than 130° F. and be returned to the tub. The curd should be stirred by hand for 10 minutes or so. This should be repeated at intervals of a few minutes until the whole contents of the vat or tub are at the required temperature. For a Cheshire cheese the ultimate temperature should be 92° F. For a Cheddar it should be about 102° F.

If it is desired to make a Cheshire cheese, stirring is continued until the curd particles are distinct, but soft. For a Cheddar stirring is continued until the curd particles are hard and distinct, with a tendency to "mat" or run together. This tightening up of the curd is due to the development of acidity.

Drawing Off the Whey.—When the curd is distinctly acid the whey should be removed. The curd should be allowed to settle and then the whey should be drawn off through the tap, or, if there is no tap, after the curd has settled the whey may be ladled or poured off through a strainer. In the latter case the curd should be put into a cheese cloth and tied up fairly tight. It should then be placed on a sieve or rack in the bottom of the cheese tub so that the whey can drain away. In no case should the curd be allowed to lie in the whey which has drained from it. If this is permitted the resultant cheese will be soapy and weak. In whichever way the curd is drained and ripened it should be opened out occasionally and cut into 4-in. cubes. This assists drainage and the development of acidity. From the time the whey is drawn the curd should be kept warm until it is ready for grinding. If the milk has been ripe the whole process should not occupy more than 5 hours and except during the heating process attention is only necessary at intervals.

Grinding the Curd.—Grinding or breaking up the curd follows when the curd is sufficiently sour or "ripe." To ascertain if the curd is ready to grind an old reaper file may be heated to a black heat. A little of the curd should then be pressed in the hand until it is solid and dry. This should be brought into contact with the heated file, and be drawn gently away. The curd will string out in fine hairs. If these are $\frac{1}{2}$ in. long before breaking, and the variety of cheese being made is of the Cheshire type, then the curd is ready to be broken up and salted.

For a Cheddar the strings should be 1 in. long before the curd is ground. A curd mill can be dispensed with if the quantity of curd does not exceed 20 or 30 lb.

The Cheshire curd, being soft, is easily broken up by hand. It should be broken up rather fine—about the size of split beans. Cheddar curd is more difficult to break. The curd should be first cut into strips with a sharp knife, and then broken up into pieces about the size of half a walnut. After breaking it should be well stirred and allowed to cool a little, after which the salt may be added. It is not necessary to weigh the curd.

Salting.—Salt should be added at the rate of 1 oz. to every 3 gal. of milk used. For example, if 12 gal. of milk are being made into cheese then 4 oz. of salt will be required. The salt should be stirred in carefully and the curd should remain until it loses its harsh condition or becomes velvety.

Moulding.—It will now be necessary to place the curd in the cheese hoop or mould. A cheese mould large enough to make a 10-lb. cheese should be 7 in. wide and 10 in. deep. The finished cheese will not be of this size, but allowance must be made for the new curd, which is open and bulky. Most makers use a special kind of cloth to line the cheese mould, but this can be dispensed with.

What is generally known as a grey cotton cloth answers the purpose quite well. This is cheap and easily obtainable, and can be used in place of linen cheese cloth.

Pressing.—The final process in the actual manufacture is the pressing of the cheese. If a Cheshire is being made the pressing should not take place till the morning following the date of manufacture. the cheese, meanwhile, being kept warm. This allows the sweet Cheshire curd to ripen somewhat, and results in a cheese having an open texture. If a Cheddar cheese is being made then pressure should be applied a few minutes after the curd has been placed in the mould. Pressure is applied in a variety of ways. The old way was to hoist a big stone or box of bricks by means of a rope and pulley and place the cheese under this. This method, however, is slow and cumbersome. Modern presses are of three types, viz., spring presses, a combination of the screw and spring, and screw and double lever presses. All, however, are expensive and difficult to obtain at the present time. Fortunately, it is not difficult to improvise a press from materials usually found on the farm. A bar of wood 6 ft. long and about 2 in. square section should be marked out by

notches at intervals of exactly 6 in. This bar can then be used as a lever with which to press the cheese. The other items necessary are a block of wood which should be nailed to the wall and a 14-lb. weight or a couple of bricks. Pressure is applied as shown in the sketch.

A—Wall ; B—Block of wood fixed on wall ; C—Wooden lever, 6 ft. long and 2 in. by 2 in. section ; D—Weight ; E—Kitchen table ; F—Cheese mould containing cheese.

The block B should be placed in such a position that the bottom of the wooden lever C is $\frac{1}{2}$ in. above the level of the cheese mould F. If cheese moulds or hoops are of different sizes they can be raised to the required position. When placing the mould in position the circular wooden follower with the square pressing block on top which goes in the mould should stand clear above the upper rim of the mould. On the top of the upper follower or block should be placed a small piece of iron rod, $\frac{1}{2}$ in. square section, of such a length that it goes easily into the mould. This rod should be placed exactly across the centre of the mould at right angles to the lever bar. This will ensure continuous and equally distributed pressure.

As the cheese sinks one or two thin pieces of wood should be placed under the top follower so that the lever is kept as nearly as possible in a *horizontal* position. If the bar rests on the mould itself then no pressure is being applied to the cheese. The cheese mould should be placed in some vessel such as a setting pan or shallow wooden tub to prevent the whey spreading over the table and floor.

When first put to press the cheese should be placed under the third mark from the wall. Later it should be moved to the second mark and finally pressed under the first mark nearest the wall, or 6 in. from the wall end of the bar. The greatest pressure is exerted when the weight is at the extreme end of the lever.

An improvised press as described will exert a maximum pressure of about $1\frac{3}{4}$ cwt. with the weight at the extreme end and the mould under the first mark from the wall. With the mould in the first position and an unweighted lever the pressure on the cheese will be about 28 lb. If the weight is placed on the second mark on the bar or lever the pressure exerted is about 56 lb. and at each mark to the right the pressure will be increased by about 14 lb. If more pressure is needed in the final stages this can be obtained by placing a brick or other weight on the end of the lever. A final pressure of 2 cwt. is found to be quite ample for a cheese of 10 or 12 lb. weight, especially if the curd has been properly ripened or soured before being placed in the mould. It is important to keep the lever in a horizontal position. A lever down at one end makes a crooked cheese, and pressure is unequally distributed. The morning following the date of manufacture the cheese should be taken out of the mould, turned and replaced with a dry cloth. Twenty-four hours is usually sufficient time for the cheese to remain in press. When taken from the press the cheese should be dipped in hot water for a minute and then be bandaged.

Bandaging.—Any light cotton cloth may serve as a bandage. The bandage is best made and put on in a tubular form. A piece of cloth should be stitched so that it can be drawn tightly over the cheese. If turned inside out before it is placed in position it will be neat in appearance when on the cheese. The cloth should be 2 in. larger than the cheese, and the inch overlap at each end of the cheese should be pasted down. If a little common fat or unsalted whey butter is obtainable the cheese should be rubbed with this before bandaging.

Curing the Cheese.—The next matter is the curing of the cheese. Any room having a moderate and regular temperature is suitable. The floor of an unused bedroom will suffice, or a dry cellar. If the room is too damp there will be growth of mould on the surface of the cheese; if too dry then the cheeses will crack. Care must be taken that no mice have access to the room when the cheeses are being cured.

A cheese made on the foregoing lines should keep for 6 months, especially if it be of the Cheddar variety.

Note.—Skilful management at three important stages in the process of cheese-making is essential to success. (1) In the first stage the milk should be sufficiently ripe or acid before rennet is added. If too sweet or too sour the results will not be satisfactory. (2) The second important stage is at the draining off of the whey. At this stage the acidity of the curd should be distinctly discernible; if too sweet then the whey will not drain away when the cheese is put to press, and the resultant cheese will be soft and spongy, have a weak and bad flavour, and will putrify rapidly. (3) The third important stage, especially when Cheddar is being made, is at the period when the curd is broken up and salted. If the curd is salted in too sweet a condition then the cheese will be soft and weak in flavour; if too sour the ripened cheese will be hard and dry.

If reasonable attention is paid to these points, and care is exercised at the other stages of manufacture, the cheese should turn out well, and be a valuable addition to the winter's food supply.

THE AGRICULTURAL PROGRAMME OF THE UNITED STATES.

THE national steps which have been taken and many individual or local efforts that have been made to increase production in this country should be well known to readers of this *Journal*. It may be useful, however, and an encouragement to British workers, to know what has occurred in the United States. It is therefore proposed to quote the following passages from the February (1918) issue of the *Experiment Station Record*, published by the United States Department of Agriculture:—

“For the first time in history the United States, along with several others of the allied countries, has drawn up a working program for agriculture, to secure adequate production. This is one of the many unusual features growing out of war conditions, and particularly of our relations and responsibilities to the allied countries. The new memorandum, issued by the Department of Agriculture in February,*

* See p. 280.

supplements the one published in August of last year relating mainly to cereals."

"Like most of the measures in this country pertaining to food production, this is not a prescribed program but comes in the form of a carefully-weighed suggestion as to the needs and means of meeting them. It is voluntary, of course, but it is hoped that it may serve to give general direction to the season's campaign and stimulate efforts in the lines in which they are most desirable. Its appeal rests primarily on the necessity of the situation, and the understanding of agriculture's part in the great War."

"In a word, the outline is 'a statement of conclusions concerning the agricultural situation and the planting needs. . . . It is offered as a recommendation for those engaged in crop and animal production, especially for the many farmers who are in a position to readjust their agricultural program in accordance with the national necessities.' In the main it is general rather than specific, except for wheat, and it is considerate of farming conditions and specialized branches. It is in no sense an office program made up on statistical and theoretical considerations, but it embodies the judgment and suggestions of agricultural leaders throughout the country. The needs and the possibilities have been viewed in the light of the conditions which prevail at this time. It is designed, therefore, as both practical and practicable, barring untoward developments of the season. It is therefore something to work to, and to join hands in seeking to attain."

"While the situation is such that chief emphasis is laid on the production of the great staple food products, with special stress on wheat and hogs, the outline summarizes the aims for securing sufficient cereals of various kinds, meat and dairy products, sugar, cotton, and other products for the Nation, its armies and its Allies. It will furnish the basis for personal appeal and guidance throughout the country, but it differs radically from the programs of some of the European countries in its lack of provision for enforcement or regulation of the industry, such as is now common there. For agriculture in the War has assumed the character of a military necessity in those countries, and although not brought directly under military control it is dominated to a large degree by its requirements and subjected to civil orders and regulations hardly less mandatory."

"The increasing extent to which these measures have been put into effect in Europe, especially in the past year, shows by

comparison the relative freedom which prevails here, and the absence of many of the real handicaps and hardships which have to be met in other countries. Here dependence is placed on individual response and the determination to resist failure, while there regulation and compulsion have been resorted to in a thousand ways new to modern times, and stimulation and direct aid have become the order of the day. A knowledge of the conditions and measures relating to agriculture in the War is of no small interest in this country, since food production has become one of the great co-operative enterprises between us and our Allies."

"The efforts made in respect to European agriculture are well illustrated in Great Britain, since that country has been peculiarly dependent on outside food supplies. . . ."

And finally, after giving an account of the farmer's difficulties in this country, and of the steps which have been taken to increase food production :—

"Evidently determination is nowhere more pronounced than in relation to agriculture. Its prosecution has become a war measure of highest importance, and the country is straining every nerve and resource to meet the necessity as now clearly seen."

"These high purposes and splendid efforts command admiration. The determination to rise above the handicaps and difficulties which surround the industry furnishes an evidence of what may be accomplished under co-operation and effective leadership. Time-honoured customs and long-established systems have been swept aside, in a country proverbially conservative and among a class slow to make radical change."

"The British farmer has had to meet harsh criticism and charges from sources unreasoning and uninformed as to the real situation and its difficulties. These have been an added burden, but the British Premier, himself born on the land, has urged the farmer to think only of one thing—his country's need, and has confidently predicted that this will enable him to win a great triumph for British agriculture and for the Empire."

"Such an example ought to prove an inspiration to us in this country, where the aims are similar and the obstacles less pronounced. We have reached the stage for adjustment in many matters and the necessity for a larger measure of co-operation in realising the desired result. The employment of every resource is necessary. To help in this accomplishment

is the opportunity of the colleges, the stations, and the vast army of agricultural extension throughout the land."

British agriculturists should be happy to feel that their American Allies in the prosecution of the great War of Liberty are able to write thus of them and their efforts, and they will certainly wish to have expressed on their behalf the high sense of gratitude and admiration they in their turn feel for the energetic, practical and unselfish action taken by America, not alone in her military prosecution of the War, but in ensuring that the food needs of her European Allies shall be fully met.

The following is a summary of the main items included in the programme of the United States for Agricultural Production for 1918 (U.S. Dept. of Agric., Office of the Secretary, Circ. 103, 19th February, 1918), referred to in the above note :—

It is pointed out by the Department of Agriculture that in spite of the large production in many directions during 1917, the situation is not satisfactory. Chief emphasis is given to the production of the great staple food products, with special stress on wheat and pigs, the leading war foods.

Spring Wheat.—An earnest appeal is made to increase the acreage under spring wheat in order that an adequate supply of wheat, both for home use and to meet the needs of the Allies, will be assured. To this end the crop is being re-established in certain parts of the country where spring wheat has not been grown in recent years. It is believed that to a small extent the acreage in oats, if necessary, could be reduced in the interest of wheat, even though this may somewhat reduce the oats for feeding to live stock, leaving the animals more dependent upon other grains and roughage. In some cases, where the acreage of spring wheat proposed cannot be planted, it is suggested that the acreage of barley might be increased, as barley is now in greater use in the United States, besides being a welcome food in Europe. Farmers are asked to give special attention to the thorough preparation of the seed bed, the selection of the best seed obtainable, and the treatment of seed where necessary to protect it against disease, in order that the maximum results may be obtained.

*Corn.**—In view of the large acreage under corn in 1917—the largest on record—no increased acreage is asked for, and slight reductions may even be made in certain sections where such reductions would free areas for spring wheat, and so benefit food production as a whole.

Pigs.—As a result of a very careful study of the pork situation it is desired during 1918 to increase the number of pigs kept by at least 15 per cent. This question has become more acute owing to the large and continued decrease in the number of pigs in the Allied countries, and also to the general shortage of fats, especially lard. Among the methods suggested for an increased production of pork are breeding for two litters a year, saving through better care a large number of the pigs farrowed, growing pasture and forage crops, using wastes, especially

* This term in America refers to maize.

town and city garbage, proper rations of concentrated foods, and finishing pigs to heavier weights up to about 275 lb.

Beef Animals.—Owing to the depletion of the European supply of cattle in consequence of the War an increased demand will be placed upon the American market, and a general increase in beef production is therefore appealed for. It is interesting to note that the exports of dressed beef and beef products have increased 177 per cent. during the past three years.

Potatoes.—The cultivation of potatoes is being encouraged, and the home consumption of this article of diet on a more extensive scale is advocated in order to release more wheat for export.

Dairy Products.—There is a need for increased supplies both for home use and for export, and this need can best be met by a fuller utilisation of the by-products of milk, more especially skimmed milk and buttermilk.

Poultry.—An appeal is made for a large increase in poultry production, especially in back yards and on farms where waste material is available and the purchase of expensive feeding material is not required.

Sugar.—An extensive increase in 1918 is not possible, largely owing to the limited amount of seed available, and suggestions are therefore made with the object of securing the largest acreage and obtaining the highest yield from the seed available.

THE TAKING OF WILD RABBITS.*

PART I.

R. SHARPE.

Damage Done by Rabbits.—No man knows better than I do the damage of which rabbits are capable when conditions permit; but a proper system of management should obviate the necessity to discuss extermination. The system which I term "proper management" may be applied to either purpose—namely, to rabbit preservation within determined limits or to outright extermination. When control has enabled the alternative policies to be compared, whichever policy is found to be the better, should be adopted. There are very many places in the British Isles where rabbits may be encouraged without the risk of damage, provided always that an intelligently conceived and properly executed system of management is adopted. Even in situations not on the face of things suitable for rabbits a valuable crop may be gathered without injury to more important interests. My own experience supplies a case in point.

* These articles have already appeared in more extended form in *The Field*.

For a number of years I hired the Stoughton Manor shooting in Hampshire. The area was some 2,000 acres, consisting of covert, farm land, and downs carrying juniper bushes, gorse, and other cover favoured by rabbits. Clearly, in my situation of shooting tenant I could enjoy none of the privileges of a ground landlord in the way of securing special favours for sport. My profits were not only derived from the produce of my pheasantries, but I also sub-let the shooting on the basis of so much per gun. Rabbits, as all know, are a great asset on a small shoot of the kind which is expected to provide sport for week-end visits throughout the season. We killed thousands of rabbits every year, but never during the whole of my tenancy was a single claim lodged for damage done to the underwood in the coverts, the responsibility resting on my shoulders. I kept all the cornfields properly netted—in fact, there was a permanent wire fence all the way between the downs and the cultivated land. When a stretch of underwood was cut I invariably enclosed it for the first year, after which it was safe, the netting being then available for moving to the next piece. I always took steps to kill off the bulk of the rabbits in the coverts not later than the end of November. This prevented the gnawing of the hazel and its consequent destruction. Shooting did not suffer, for I always left till last the rabbits which were least likely to do damage. By judicious management I could always show a decent day's sport right up to the end of the season. In proof of this assertion I might mention that some old accounts I recently looked up showed receipts for rabbits sold in the month of January to have been £87 odd.

The fatal mistake which is nearly always associated with damage by rabbits is the leaving of large stocks in the coverts during the hard weather. In such circumstances they are bound to do serious damage. Those of my rabbits which had been allowed to remain on the downs were fed at such times by the cutting down of juniper and gorse bushes. These, when strewn on the ground, provided ample food, so removing the temptation to wander. Rabbits must get hard food from somewhere during periods of frost and snow, and if they cannot find it in their regular haunts they move to places where it can be obtained. Those who complain of the destructive habits of the rabbit should always ask themselves what harm rabbits can possibly do in December if the stock has been steadily killed off during the months of September, October, and November till nothing but the barest breeding stock remains.

Definition of Good Management.—The prime essential of sound management is that rabbits shall be killed off early. What happens at present in a large number of places is that thousands are about at a time of year long after the proper season for killing them. They soon deteriorate in food value, for when the month of March opens breeding operations commence. Operations should commence towards the end of August, though admittedly this date is full early. Consignments must be sent daily to the dealer, and even then it is difficult to prevent fly-blows. The kind of weather experienced must influence the action taken. Snares set in the early stages of the season must be placed well away from the covert or hedge-row from which the rabbits emerge; this because very small rabbits seldom travel so far from home as do the more mature ones. Snares set well out are also less likely to be knocked over by the youngsters, which oftentimes jump right through the loop without being caught.

Traps Unsuitable for Early Operations.—Traps are quite inadmissible for early operations, because, being set in the holes, they catch a preponderance of young rabbits. These, as all know, are the first to come out. The older ones which follow later not only escape for the time being, but they betake themselves elsewhere to escape the danger so prominently brought to their notice. Covert being at this season plentiful they experience no difficulty in finding fresh accommodation. For the reason stated, the trap should not be brought into use until November. The desire for extermination supplies the only justification for exceptions to this rule. Snaring can, of course, be done all the year round. Less practice is required to become a good snarer than a good trapper. This applies particularly to the rate of working. There are many who object altogether, on humanitarian grounds, to the use of the trap, but the very legitimate objections lodged against trapping are traceable to errors of method rather than to inherent defects in the system. A similar remark applies to the objections lodged on behalf of the fox-hunting interest. The law directs that traps shall be laid inside the burrows, but there are many who actively object to the trouble involved in obeying the law.

Scarcity of Skilled Trappers.—The *personnel* available to carry out the necessary programme is growing scarcer every year, not merely as a result of the War but as part of a process which has been at work for a much longer period. If agricul-

ture is to be set upon a proper footing, the auxiliary work of managing rabbits and keeping down vermin must not be neglected. Many causes have been at work during recent years to diminish the supply of competent trappers. One of them has been the increasing cheapness of guns and cartridges, and the consequent development of shooting rabbits bolted with the aid of ferrets. Another explanation is the modern craze for huge bags of pheasants. The younger generation of keeper has graduated in the pheasant field, his tuition having in the majority of instances begun and ended with pheasants. No more fatal mistake could possibly be made, for even pheasants are useless if turned out into woods swarming with vermin of every description. The prime essential in a keeper is that he shall be a first-class trapper. Rabbit trapping is but one branch of the art, but if rabbits are deemed worthy of attention as a source of food supply, justifying cultivation, then trapping must extend its functions in the direction of removing the enemies of the rabbit, which are also the enemies of the farmer.

The keeper of the future may, perhaps, be recognised as the faithful servant of agriculture. In the past his services in that direction have only been appreciated by the more discerning. Perhaps some day his duties and responsibilities may be so enlarged as to raise the status of his profession in accordance with the services he is so well fitted to perform. Meanwhile, the sons of keepers find few incentives to follow their father's calling, whilst those who have attained responsible positions have too often left out the most important department of their training. One of the reasons why trapping has so largely become a lost art is that the use of traps is discouraged in coverts on account of the disturbance their use occasions. There is no reason why trapped rabbits should scream and otherwise cause the agitation which is held quite rightly to breed nervousness in the sanctuary of the pheasants. But as the use of the lamp at night cannot altogether be dispensed with when dealing with rabbits the snare applied in the open is to be preferred. Trapping is vital, but a knowledge of details is necessary to avoid the mistakes of application which so frequently result either in unqualified prohibition or in half-hearted employment.

SNARING OF RABBITS.—General Principles.—To obtain success in the snaring of rabbits a certain number of rules must be rigidly observed. To the novice many of these may appear immaterial, but experience has proved that they cannot be disregarded. For the most part they are based on the acute

sense of smell possessed by the rabbit. The time of day for setting the snares, the practices to avoid whilst setting them, and the sundry adjustments to weather conditions are all related in the end to this highly specialised gift. Beginners are inclined to scoff at the idea, but until they recognise its undoubted truth they will never attain success. Let anybody try to drive rabbits against the wind towards a line of guns, or try to stalk one of these animals down wind, and a valuable object lesson will be gained. Other rules of procedure are based on the instinct possessed by all animals of inoffensive habit which have survived and multiplied in a wild state. The snare must be skilfully concealed; its position must be constantly changed in order that familiarity may not cause the rabbits to avoid it.

Time of Day for Laying Snares.—All snares should be laid before the mid-day meal, a sufficient interval being so given for the smell left by the hands to disperse. If, before starting to set the snares, the hands are plunged in damp soil and well rubbed, so much the better. The wearing of gloves is not recommended. Those unused to them perspire freely under the covering, the result being that a well-used pair of gloves leaves more scent on the things touched than do the bare hands. The scent left on the hands by smoking or by contact with a pipe is readily communicated to the snares, and the pungent odour remains on them for a long time. The snarer must, therefore, forego his smoke until all his wires are down. The first rule as to laying snares is thus based upon the keen sense of smell possessed by rabbits.

Set Snares with Reference to Wind Direction.—In selecting a site for operations the snarer should choose a field or piece of land over which the wind is blowing from the home of the rabbits towards the snares. Not only will a rabbit travel down wind at a far greater pace than up, but it will continue travelling freely till enmeshed in the snare, unwarned by the escaping odours which travel the other way. If a rabbit is not travelling fairly fast it does not get caught, for a slow pace enables it to detect any obstacles set in its path. If a down-wind is not available, then try for a side-wind, which comes next in point of desirability, though it is not nearly as favourable as the first-named. The most suitable night for a good kill is one which is not too dark, with a gentle breeze and light clouds scudding across the moon. There is always a chance of the wind shifting after the snares are set, but this cannot be provided against.

Quick Laying of Snares very Important.—Much of the advice here given is directed to the promotion of great speed in setting snares. With all advance arrangements well made a man who has become fairly proficient at the business can lay from 75 to 120 snares in the hour. The higher speeds can only be reached on fairly good setting ground, with runs frequent and the earth receiving the pegs in a docile spirit. On bad pegging ground, or where there are a few rabbits about, the total of snares set in a given time is much lower.

Drive all Pegs with a Mallet.—When only a small amount of snaring is done the pegs are usually driven home with a stamp of the heel, but this practice is not one that can be generally recommended. Balancing on one leg whilst using the other as a hammer disturbs the grass unduly; the peg is not so cleanly driven and is more likely to come away if the rabbit struggles; finally, the boot is soon injured by performing this unaccustomed duty. The writer prefers, and has always used, a small but heavy mallet with a boxwood head, or a hammer of his own design, having a broad head, and a spike at the other end for opening hard ground for the insertion of the pricker.

Height of Snare above Ground.—As a general rule the loop of the snare should be fixed about $4\frac{1}{2}$ in. above the ground. If the herbage is very short 4 in. is high enough, but if the grass is extra long the height of the wire may be increased to $5\frac{1}{2}$ in., or, in extreme cases, 6 in. A good deal of discretion must be used at all times, and note must be taken of the fact that rabbits leap higher if the grass is wet as a result of dew or rain. The wire should be placed centrally above the run, but as the pricker must never obstruct the line of traffic the loop must be set slightly aslant.

How to Fix the Pricker.—The pricker must be planted firmly in the ground about $1\frac{1}{4}$ in. to one side of the run, but slanting slightly inwards so as to hold the wire in the right position without introducing the necessity for bending. Many rabbits are lost by the pricker giving way at the first pull on the snare wire. At this critical moment it should hold fast, because by so doing it enables the noose to draw up quickly. If the pricker gives way the extra slack provided delays the tightening of the snare and affords the rabbit an opportunity to back out of the wire and so escape. Not only is such a rabbit lost, but it has learnt a lesson which will lessen the chance of its capture by the same method in the future. Prickers which lie too close to the run are liable to be kicked by the hind foot of the rabbit in the

act of landing on all fours. A pricker set well to one side and firmly planted thus escapes or resists disturbances at the critical moment when the rabbit is due to leap into the snare

How a Rabbit Jumps.—The necessity emphasised in the previous note of planting the pricker firmly and to one side of the run will be made apparent by devoting a paragraph to the action of the rabbit in running. Nineteen persons out of twenty wrongly interpret the characteristic foot-marks of the rabbit as imprinted on snow. They correctly diagnose the pair of side prints as those of the hind feet and the two centrally disposed, one in advance of the other, as made by the fore feet. Where they go wrong is in thinking that the direction of travel is with the front feet foremost, whereas the hind feet are planted on the ground well in front of the fore feet. In other words, the rabbit is travelling in the opposite direction to that which appears at first sight to be the case. As the hind feet can only reach the front position by leaving a central gap free to accommodate the fore feet, their wide separation is explained, also the fact is made clear that if one of the hind feet kicks the pricker it does so whilst the rabbit's head and body are still well to the rear.

The studies of rabbit tracks shown in Fig. 1 have been made by Mr. Frohawk for the purpose of explaining the distinction between the long and the short beats. The arrow denotes the direction of travel, and the measurements at the side show how the distance between the hind-foot tracks of the rabbit and of the fore-foot tracks varies with the speed. The 18-in. separation shown in Fig. 1 is achieved at full gallop, the fore feet no doubt striking the ground whilst the body carries forward under the power of momentum, the hind feet striking the ground later. The one-foot separation, as shown in Fig. 2, represents the ordinary rate of progress along runs, the hind-feet tracks being still in front, although the two pairs of feet would be likely to strike the ground more nearly simultaneously. Fig. 3 denotes the sitting position. A rabbit run consists of a series of beats or jumping places at more or less regular intervals, the variation in their spacing depending on the degree of flatness of the ground and other causes. The long beats are the longer of those beaten-down places, denoting that the rabbit frequently jumps from one to the other with one or other of the wider degrees of separation between front and hind feet contacts with the ground. As rabbits use the same beats whichever way they are running, the long beat is well defined. Short beats occur promiscuously in runs, perhaps at intervals separated by a series of five or six long beats. Snares should always be set in the long beat.

Set Snares in the Long Beat of the Rabbits' Run.—Full appreciation of the facts stated above is necessary in order to distinguish the long from the short beats in a rabbit run, and so be sure of setting the snare in the long beat. A snare so set is equally successful in catching the rabbit when travelling on the outward or on the return journey. The snare should be set in the middle of one of the extra-beaten places. Then, from whichever direction the rabbit arrives, its chest nearly touches the bottom part of the snare and its head is practically through the loop. If it does not scent danger the next bound draws the

loop tight round its neck. Occasionally a rabbit will be caught round the shoulders, with one or even both legs in the loop. Either signifies that the snare has been set too low. Should the loop fasten round the loins of the rabbit only a firmly-planted peg and sound tackle will retain it. Snares set in the short beats get knocked down as the rabbit in its leap passes over the top. The same will often happen in the case of correctly-set snares, but this mishap is nearly always caused by one of two things—rabbits chasing one another or fleeing from danger, real or supposed. Under the last-named conditions the regular beats are not used, long leaps being taken which leave as many as three or four of the intermediate ones unused. Chance then decides whether the snare is located at the beat used or whether it is brushed aside by contact with the rabbit's hind feet in the course of its jump. Correctly-placed snares command success in the majority of cases.

Never Kneel on the Ground.—A rule to be observed without exception is to avoid kneeling on the ground when setting a snare. The practice of kneeling tends to "foil" the ground close to the snare, and, as previous notes have made clear, the snare is set at the points in the run where the animal lands on its hind feet and braces its muscles for the next leap. An interval of time, depending on the rate of travel is devoted to these processes and, although short by measurement, it represents momentary stillness compared with the rate of movement during actual leaps. If the rabbit scents danger at these moments the pause is prolonged for observation purposes.

The Real Secret of Success.—The real secret of successful snaring is to remove the wires to fresh ground after they have been in use for one night. Their next place of setting should be situated up to half-a-mile from the first, the main consideration being the certainty that operations shall be conducted against a fresh lot of rabbits. Many snarers who agree with the general principle embodied in this advice affirm that the snares may well be left in the same place for a second night. They support their argument by the quite accurate assertion that fully half the first night's catch can be looked for on the second occasion. With this I agree as far as the first time over the ground in early autumn is concerned. But the penalty is paid on the occasion of the second time over, and the evil results are at a maximum if several nights of continuous snaring have been indulged in. What happens is akin to the case of a man who is cutting across a lawn and suddenly trips over a

hoop which has been laid down to discourage such short cuts. Though few will afterwards go the long way round, they never get caught a second time. Snares which are left for long in one place become familiar obstructions; rabbits get to know them quite well and soon learn to jump over them. The habit is extended to all other snares wherever set. A man working 100 snares on the one-night system will kill more rabbits than he who works with 300 and leaves them for a series of nights on the same piece of ground.

Rabbits Temporarily Desert Ground Continuously Snared and Trapped.—I know of nothing which will drive rabbits away more effectively than snaring continually on the same area. This is not due to the number caught but to the state of nerves induced by the screaming of the occasional rabbit which falls a victim. Rabbits terrorised in this manner desert the ground for the time being and take up their abode in all sorts of unlikely places, to return in due course to their breeding haunts and wreak damage on the farmer's crops. When catching is the end in view scaring as an involuntary substitute is surely bad business.

Number of Snares that Can be Properly Attended to.—A man working single-handed should not be expected to work more than 200 snares at a time, and this only on good ground. In favourable circumstances a skilled man can easily attend to this number, moving them by noon each day to the selected new ground. He must devote his whole attention to the work, and must have available an ample space of ground. On a farm which is not very big, or on extensive farm lands where the proportion of rabbit ground is limited, a smaller number of snares would be used, this principally because too large a total would complete the rotation too quickly. In some of these cases it would pay best to set the full total of snares and to give the land a rest after completing the round. Where the full allowance of snares would cover the whole ground available at one sitting they should be taken up in the morning and be set aside for a clear week.

Night Visiting of Snares.—An important advantage of the one-night or intensive system of snaring is that the snares, having been set over a limited area and so recently that their position is well remembered, can be visited at night. Such visits should be paid not later than 7 p.m., the object being to remove all rabbits which have been caught. On very dark nights a bull's-eye lamp should be carried, but its use should be avoided whenever possible. Exceptional conditions may necessitate

a variation of the hour at which the night visit is paid. For instance, should it be raining hard up to six or seven o'clock and then suddenly clear up, the rabbits which have been confined in their burrows up to that time will want to come out and make up for lost time. A visit paid at the fixed hour will in such circumstances not only be fruitless, but will destroy the prospect of an excellent catch. Hunger will cause the rabbits to leave the covert much more freely than on ordinary occasions, and, as has already been explained, the faster they travel, within reason, the more certain they are to be caught. An interval of from one to one-and-a-half hours should accordingly be left from the clearing of the weather to permit full use to be made of such exceptional opportunities when they arise.

The Evening Visit Discourages Foxes.—Foxes are a great source of loss on ground where rabbits are snared on the continuous system. The large number of wires laid, the considerable area covered, and the relatively small proportion of catches operate together to discourage night visits. When the one-night system is practised the result fully repays the evening visit. The caught rabbits are at once dealt with, and they are not left on the ground to attract foxes by their cries. Not only is this particular invitation to foxes removed, but the passage of a man over the ground discourages visits from foxes during the remainder of the night. If the duty of nightly visits to the snares is faithfully performed, foxes are less likely to develop the habit which, once acquired, means considerable loss and inconvenience.

Influence of the Moon on Snaring.—When the moon is at its brightest, say, from the ninth to the eighteenth day, it will be found that rabbits are not caught with the usual freedom. This is especially the case on bare grass lands. The explanation is, of course, the greater visibility of the snares. During such periods setting should be carried out on ground provided with sufficient herbage to cover the pricker. Stubble fields or land carrying short heather and rushes are cases in point.

General Programme of Working.—To keep rabbits under proper control it is necessary to snare with all possible energy until the stock on the ground has been reduced to the desired limits. The main consideration is the gathering with all possible speed of the rabbits marked out for the purpose. Delay spells loss of rabbits, injury to crops and plantations, deterioration of condition, and a host of other evils. The methods by which prompt and early catching are attained are at once the most humane and the most profitable. By snaring each piece of ground on the one-night system, with suitable intervals between the successive operations, the routine adopted on each occasion may be adjusted to fit the stage reached. The order of working which suits the first stage is unfitted for the second, and so on down the series. Finally, when the third or fourth visit proves that the work has been properly done, ample time remains for

conducting those other clearing-up processes upon the success of which so much depends. There are few who realise the importance of commencing to take rabbits early in the season, as soon in fact as they are fit for market. The rabbits may then be reduced to proper proportions by the end of February. When that is done stocks may be reduced to an abnormally low level without diminishing the following season's production. The explanation is simple. If, through bad management, snaring operations are continued all through March the commencement of breeding is held back until well into April; but if the rabbits are left alone after the end of February early litters are the rule and a clear month is gained. The progeny of these early litters will themselves bring up two or three families in the late summer and early autumn. Thus all aspects of the situation dovetail into the scheme of management here recommended. The underlying policy is to produce a maximum crop of rabbits during the season of plenty and to harvest it before scarcity engenders destructive habits.

Placing the Snares for the First Time.—When setting snares for the first time in the season I choose a line about 25 yd. away from the covert or fence containing burrows, and I put snares into all the short runs as well as the main runs. If the rabbits are very numerous I put two snares and at times even three into the main runs at about 15 yd. apart.

Second and Subsequent Times Over the Ground.—For the second set I take a line beyond the first, say, 60 yd. further out, always providing that the runs show this far out into the field. On the occasion of the third attack I ring the changes on Master Bunny and set the snares closer in to the covert, always avoiding, if possible, the exact line of any previous set. The longer the ground is rested the better the results will be; but if all the available ground has been gone over once in the course of a week the interval so provided justifies returning to the original spot and taking the remainder in due order. Not less than 10 days' interval should be allowed between the second and third sittings. As the number of rabbits decreases so the number of runs diminishes, as also does their "brightness." On the third and fourth times over only half the number of snares previously utilised will be found necessary. When dealing with the ground for the fourth time the snares should be set in a more haphazard way—that is, not in any particular line. Some may be set quite close to the covert in the brightest of the runs, others can be put far out into the field.

Intercept Rabbits Travelling to Distant Feeding Grounds.—Occasionally rabbits will travel long distances for the purpose of feeding on a crop of clover or it may be a field of roots. In the course of their journey they may have to cross an intervening field. On this they leave a series of parallel routes indicating a far-off destination. Such opportunities should be utilised to the best advantage, for good hauls are often

obtained. As all such runs will be very bright, each should be set with three snares. In the best main runs even four may be accommodated, the nearest wire to the covert or home of the rabbits being a minimum distance of 70 yd. or 80 yd. away. The other wires in each series may be spaced 20 yd. or 25 yd. apart. In a case of this kind the field which forms the particular attraction should be visited on the way to the snares. If a little noise is made by kicking against stones or by clapping the hands any rabbits which have passed the wires will be sent scampering home, so adding materially to the catch.

Snaring on Grass Land Exhibiting Plough Furrows.—Many grass fields bear the marks of bygone ploughing, and fields carrying ridges and furrows are especially favoured by rabbits. When setting snares in fields of this kind I always endeavour to choose the beat from which the rabbit takes off when jumping the furrow. At such places it takes a leap rather longer than ordinary, with the result that the noose is drawn tight before he lands on the other side.

Arguments in Favour of Knotted Snares.—The arguments in favour of knotted snares are so strong as to justify the general adoption of the practice for all snaring whatsoever. This means that the wire should be knotted about 5 in. from the eye to prevent it from pulling up quite tight. Strangers who have witnessed the process of gathering rabbits caught in ordinary snares have very naturally deplored the cruelty inseparable from the process. Common sense tells even the most kind-hearted that the tortures inflicted will remain a necessity until equally effective methods of a non-objectionable order can be devised. Such persons nevertheless regret that improvements in detail are not more often experimented with. The chief suffering due to snaring as commonly practised is attributable to the semi-strangulation which follows the tight drawing up of the snare. Not only is the windpipe compressed, but the external blood vessels are also constricted, with the result that the rabbit's head becomes swollen. It has been alleged that rabbits which have suffered in this manner are unwholesome as food. Though my own experience does not support this contention, I agree that the simple knotting of the snare-wire would prevent the worst effects from developing. Especially would these be minimised if the recommendations in the direction of lifting snares daily and visiting them at night were adopted. The allegations referred to above might, of course, be true if the snared rabbits were not gathered with due punctuality. The unwholesomeness

of the food would then be due to neglect of prompt gathering and not to the method of capture. At certain seasons of the year, particularly in the autumn, knotted snares permit very small rabbits and also mother rabbits suckling young to be released.

The Knotted Snare Serves for Taking Rabbits Alive.—Very often it happens that live rabbits are required for re-stocking warrens or for refreshing the blood of a stock deteriorated by in-breeding. The knotted snare suffices for this purpose, hence an important testimonial to its humane possibilities. The 5-in. distance of the knot from the eye is right when certainty of capture is the first consideration, but it should be increased to $5\frac{1}{2}$ in. when capture in an uninjured state is more important. Rabbits which have been caught up in the manner suggested should be carefully examined to note whether their hind legs have been injured by entanglement with the wire. Whenever the snare is found to have cut into the flesh the rabbit should be killed, for even trivial wounds of this nature are liable to end in the leg rotting from gangrene.

Snaring Rabbits in Coverts.—Though rabbits lying out in coverts are usually reserved for shooting, there are times and places when the snare can be used with advantage. With the present shortage of cartridges the system is worthy of description. Snares may be set in all the runs in a covert, following which the rabbits may be driven to and fro with a steady "no chase" dog. It is really surprising what a number of rabbits may sometimes be taken in this way, more particularly in large coverts furnished with broad rides. Such snares should be set fairly high, say, 5 in. from the ground, and all the main runs should have two snares, set for preference one on either side of the ride. In both instances they should be set in the first long beat beyond the edge of the ride. The method here described is especially fruitful after going over the burrows in a covert with ferrets and gun. For several days following this operation the rabbits which have escaped lie out. Especially is this the case if the holes are well stopped after ferretting. When circumstances make the step advisable I see no reason whatever why the burrows should not be systematically "stunk out" beforehand. The effect is equivalent to that of ferretting. "Stinking" has special advantages of its own in the case of large and difficult burrows. Rabbits when hustled in the coverts run much more freely than when moving undisturbed in the open, hence they fall ready victims to snares set in those places.

RABBIT TRAPPING.—Trapping is the Most Effective Means of Taking Rabbits.—Granting always that the trap should not come into use till the month of November, it is from then onwards the most effective instrument of proper rabbit management. A proviso to this general statement is that the ground to be worked must be suitable for trapping operations. That is to say, the soil must be of a sandy or loamy nature such as

permits of neatly covering the trap after it has been set in place. If the work is properly carried out in all its details the trap is quite as humane as the snare, if, indeed, it is not more so. Winged game and foxes are immune from the trap, but only provided that it is set well in the mouth of the burrows. Of course if traps are set outside the burrows nothing is safe from them. Few men who know their work ever set the trap in any other way than under cover, the exceptions being confined to those who to save trouble disregard the teachings of their own past experience.

Traps as an Instrument of Rabbit Preservation.—Contradictory as the idea may appear traps must be considered not only the best means of catching rabbits, but also the best means of maintaining a plentiful stock on the ground. The reason is plain to see. Traps not only catch rabbits, but they also catch the vermin which frequent rabbit earths. Rats, stoats, weasels, poaching cats—all fall victims to the trap set for rabbits. These animals in their several ways prey upon the rabbit, and are an important means of reducing the number available for human consumption. Very little trapping of any kind has been done during the last year or two. An alarming increase of vermin has resulted. The ultimate consequences are liable to be very serious if concerted measures are not immediately taken.

Best Form of Trap.—I always prefer to use for rabbits the ordinary size of trap with 4-in. jaws, though I am aware that many prefer a size smaller. All traps should be carefully examined before putting them into use, faulty welds in the chain and cracks in the S-hook being the defects most often found. If the swivel does not turn easily it must be worked till quite free. Oil may be used for the purpose, and perhaps fine emery. All traces of oil should be removed as soon as the desired freeness of working has been imparted. Traps wanted for immediate use should if possible be freed by the use of water. Complete immersion is necessary to ensure penetration into the joints. Much the best means of quickly cleaning a delivery of new traps is to place them in a kitchen copper and boil them for an hour or more. The scum and grease which rise to the surface should be removed. Following this treatment traps may be used at once.

Some Hints as to Pegs.—Wooden pegs are best for anchoring the trap chain to the ground. No fixed rule as to length of peg can be laid down; far better is it to be provided with an assortment of lengths to suit the various circumstances. The greatest length of peg likely to

be required is 16 in., though a length of 12 to 13 in. suffices for hard retentive earth. Endless trouble will be saved if from the start each peg is secured to the ring of the chain by a simple staple. Otherwise pegs are always dropping out, and as a rule fresh ones have to be made on the spot. These, at best, would be indifferently fashioned, and would not in any case have the benefit of seasoning. The pegs are driven into the ground by means of the round knob forming the handle of a proper trapping spade. This knob must be encircled by an iron band to prevent splitting. Mallets are useless for driving trap-pegs, for the reason that the peg as well as the trap must be set in the mouth of the hole for reasons explained below. The driving process in the conditions present resolves itself into bumping the peg into the ground by means of the up-ended spade.

Value of a Sieve.—For rough and stony or chalky ground a trapping sieve is of the greatest value, because it keeps small stones clear of the trap. The presence of even one of such is sufficient to prevent proper closing. The sieve, moreover, saves handling the soil, and it distributes its contents in the form of a mixture which blends well with the surrounding earth. To assist this important quality of blending I prefer to load the sieve with the soil actually removed in setting the trap. Some trappers reject the soil so removed if they judge it to be too full of stones, and they gather more sandy material from another place. Often this soil from a distance is of another colour, and possibly has quite a different smell. Rabbits anyhow seem to perceive the difference.

Where to Set a Trap.—The place to select for laying the trap is just inside the opening of the burrow. Careful examination will always show the position of the "beat," which is used equally for entry and departure. In cutting out the cavity to receive the trap first plant the spade across the hole at the extreme distance to which the trap will reach. Press it home so as to cut the soil about 2 in. deep. Then run the spade along each side, carrying the cuts from the far end towards the front of the hole. The total length so cut should be about 1 in. longer than the trap. The soil should next be removed to a depth of about $1\frac{1}{2}$ in. The peg must then be driven into the centre of the space formed to receive the trap, and not on any account outside the hole. It should be driven flush with the bottom of the excavation and in such a position that the under-arm of the trap will eventually rest on the head of the peg. All traps should be set lengthwise in the holes and not across. If the latter is done it often happens that a rabbit treading on the outer edge of the pan will spring the trap, but not get caught, as the jaw throws the foot clear. These occasions are indicated by the finding of a bit of fur in the trap.

Reasons for Placing the Peg under the Trap.—Very important reasons underlie the advice given with regard to the position of the peg. A peg driven outside the hole and away from the trap prevents the

rabbit, when caught, from obeying its natural instinct to draw back into the hole. When the peg is placed in the hole the rabbit can retreat, dragging the trap with it the full distance allowed by the chain. In this position the rabbit does not struggle to anything like the extent it would if gyrating around a peg set outside the hole. Safely hidden its fatalistic tendencies cause it to remain quiet, suffering a minimum of pain and not tempted to scream. I do not hesitate to say that ten per cent. of the rabbits which are trapped outside the hole twist off their legs and so escape in a mutilated condition. An important advantage of laying the trap inside the hole and not in the run outside is that should heavy rain come on after the traps have been set the covering of soil is not washed off the pan. I have even known rain to spring a lightly held pan. In frosty weather also, all traps set outside the hole are liable to be put out of action by freezing of the soil used for covering. In the mouth of the burrow the frost is seldom sufficiently intense to freeze the soil, and, moreover, the drier situation diminishes the amount of moisture in the soil.

A very important advantage incidental to placing both trap and peg in the position indicated is that foxes do not pull the rabbits out of the traps. They do not even attempt to scratch them out of the hole. The poaching dog has also to be considered. It will patrol the traps night after night, and drag the rabbits out wholesale. If a rabbit can draw well back into the hole there is little risk of wholesale losses from this cause, for even if the dog is doing its worst the time required to scratch out a single rabbit is considerable. Such dogs are usually chary of going any depth into a hole. Most of them have been caught in a trap at some time or another.

Special Hints on Laying Traps.—Several minor points need watching. Reference has already been made to the importance of a firmly-planted peg. After the peg has been driven home it should always be tested at once. An insecure peg may sometimes allow the rabbit to draw it inside the hole from where it can only be recovered by digging. After the peg has been tested the trap should be set as "light" as possible. This operation must be delicately performed to ensure that the jaws shall be released at the first contact of the rabbit's foot on the pan. If the "beat" has been properly located the jaws close on both front feet. The trap having been set to the required nicety it must be seated firmly in the prepared position. This is important, because a trap with any rocking tendency may topple over or move if the rabbit should happen to tread on the spring or jaws instead of on the pan. The soil should next be packed with a fair degree of firmness around the jaws. After that the spring should be covered, care being taken that the earth built up on either side should give as solid support as that lying on the spring itself. Should the soil be left in a compressible state the rabbit will know that something is wrong. A moment's consideration will show that this must be so, because the earth is always solidly compacted in

such places. If the soil is nice and fine there is no need to use the sieve at this stage. Whilst covering the pan I always insert a piece of stick made for the purpose to prevent the accidental springing of a lightly-set trap. A second piece of stick is used for smoothing down the soil, so that it shall present as natural an appearance as possible. If all is done in a workmanlike manner the earth is firm everywhere except in the critical place inside the jaws, where the pan is situated. The stick for preventing accidental springing of the trap is removed when all is complete.

Avoid Trapping Small Breeding Holes.—In trapping for rabbits it is well not to bother to set in the small breeding holes which show only one or two outlets. When large burrows are near such places do not often contain rabbits. Small holes, if left undisturbed, find tenants in due course, for the trapping of the larger burrows causes some of the rabbits to shift their quarters, and many of these retire to out-of-the-way places of this sort. When frost sets in and ordinary trapping ceases these small burrows fully repay attention, but they should be dealt with by means of ferrets and nets.

Trapping Large Burrows.—In the case of an extra strong burrow all holes which will allow of the trap being set inside the mouth should be set. Bolt-holes should be properly stopped. A mere sod of turf turned over them is not sufficient; they must be stopped for fully a foot in depth, and the material must be well rammed home with the knob end of the trapping spade. Otherwise rabbits will push their way out, and the haul will be spoilt as far as the particular burrow is concerned. Where rabbits are numerous traps may be left in the same burrow for as long as four nights, since many of those inside will not come out for the first night or two. Where possible, traps should be worked in batches so as to equalise each day's duties. For instance, when working, say, six dozen traps, two dozen may be moved to fresh ground each day. This allows three days in each situation, circumstances deciding whether it is long enough.

Stopping Up.—As the ground must be trapped at least twice each year, the task on the second visit is much simplified if at the time of removing the traps all but the three or four best setting holes are well stopped. When the time comes for the second set a much smaller number of traps is required, the rabbits being, of course, fewer. After the second time over the ground all holes should be thoroughly well stopped. Those afterwards scratched out indicate the number of rabbits left

behind, the result deciding whether a third visit is necessary. When holes are being stopped great care must at all times be taken to ensure that no bolt-holes have been missed. Once in a way these may be found a considerable distance from the main burrow. A single bolt-hole which has been overlooked will allow a large number of rabbits to escape.

Procedure for the Evening Visit.—Traps, like snares, should be visited in the evening, but in the case of traps the round may be made an hour earlier than that recommended for snares, say any time after six o'clock. A bull's-eye lamp will be found necessary on these occasions. Preferably, it should be provided with a shutter to mask the light when passing from one set of burrows to another. As traps which have caught rabbits must be re-set in the course of the round, either an assistant must be available to hold the lamp or a stand must be carried which enables the beam to be rightly directed. Neglect to re-set traps which have caught rabbits, or which have sprung without result, means loss. Not only does the rabbit escape which might have been taken, but others pass out by the same way. A properly-trapped rabbit blocks the hole in which it has been caught. Here, incidentally, is another reason in favour of laying both the trap and the peg inside the mouth of the hole. Traps when re-set must be placed exactly as before. In loose soil or sand this may present some difficulty, but with the peg as guide the risk of error disappears. Correct setting in the position previously chosen is called for by the necessity to lay the trap in the true beat. There is one just inside the hole and another outside. Should the trap happen to be re-set between the two the rabbit will hop or jump clean over it and so escape.

The Morning Visit.—This visit should be paid as soon as daylight is sufficient to collect all rabbits caught, re-set the traps, hang up the rabbits, etc. (The reason for dealing at once with caught rabbits is that any which may have got outside the holes will struggle violently to free themselves the moment daylight appears. During the dark hours of night they remain comparatively quiet.)

Removing Trapped Rabbits.—A rabbit which has been caught by means of a trap set in the manner here recommended will generally be found half an arm's length down the hole. In removing such a rabbit care must be taken not to withdraw it by pulling on the chain or trap. By so doing unnecessary suffering will be caused to the rabbit, and, moreover, the foot may be pulled off, so allowing the rabbit to escape. In all such cases the right hand should be passed into the hole, and the ears be gripped tightly. This done, the spring of the trap should be drawn gently forward with the left hand, the rabbit being eased out until it can be secured, when its neck should be broken.

(To be continued next month.)

"BROWN ROT" OF APPLES.

H. WORMALD, M.Sc. (Lond.), A.R.C.Sc.

Mycological Department, South-Eastern Agricultural College, Wye, Kent.

THE DISEASE ON THE TREE.—During summer and early autumn apple trees are frequently attacked by a disease which produces on the fruit brown areas which gradually increase in size until the whole apple is affected; meanwhile, small pustular swellings appear beneath the skin and soon burst through as yellowish, powdery, cushion-like outgrowths, usually in concentric circles. The diseased apples begin to shrink in size and the skin becomes wrinkled (see Fig. 1). Such fruits, when hanging loosely, are easily detached and many fall to the ground during a high wind; the rot continues to develop on these windfalls, and more pustules are produced, to act as a possible source of further infection. When, however, a diseased apple is in contact with other apples or with a branch the pustules produced at the point of contact become adherent and may so attach the apple to the tree that some little force is required to detach it.

Method of Attack by the Parasite.—The disease is caused by the fungus *Monilia fructigena*, Pers. (= *Sclerotinia fructigena*, Schroeter). The powdery pustules which sooner or later appear on the affected apples are outgrowths of the fungus growing in the flesh of the fruit, and each consists of numerous chains of spores or reproductive bodies. The spores readily fall apart and are easily scattered by the wind or carried by insects to other apples. When they gain access to the flesh of an apple through any cut or rupture of the skin they germinate within a few hours, producing fungal threads (*mycelium*) which develop within the tissues and cause the characteristic "brown rot."

The rapidity with which the rot travels through the apples is illustrated by an experiment which was carried out in the plantation at Wye College in the summer of 1917.

On the 24th of July, while the apples were actively growing, and about 1 in. in diameter, ten of them were artificially injured by making a single puncture through the skin by means of a sterilized needle, and inserting in each puncture spores of *Monilia fructigena*, taken from a pure culture of the fungus which had been grown in the laboratory. Two days later it was seen that a brown rot had already made some progress, for round each puncture there was a discoloured area varying from one-eighth to half an inch in diameter.

At the end of six days from the beginning of the experiment about half the surface of each of the ten inoculated apples was brown, while the

rest of the apples on the tree showed no trace of the rot. A few pustules had by this time appeared on each of the ten, in a zone at about half an inch from the puncture; they were of a buff yellow colour, and when fully developed were about one-tenth of an inch in diameter.

Nine days later the whole surface of each inoculated apple was brown and bore numerous powdery pustules. Strong winds which occurred about this time caused nine of the apples to fall; the remaining one had been in contact with the branch and the pustules on that side had so attached themselves to the bark that although the stalk of the apple had become almost detached from the fruiting spur the fruit itself remained fixed to the branch by means of the pad of fungal threads.

When an infected apple is in contact with others on the tree the latter may become infected by contagion, and frequently a bunch of apples is found which shows fruit with the rot at various stages of development. Fig. 1 is a photograph of such a cluster of apples obtained from a tree of the Warner's King variety in late summer (mid-September). The disease had commenced in the small withered apple above; below this and in contact with it is another apple which had evidently been affected for some time, as it is much shrunken and wrinkled. The rot had extended from this apple to the one on the left, which, at the time the photograph was taken, was permeated with the fungus and bore numerous powdery pustules; but it was only very slightly shrunken and its surface showed but little wrinkling. On the right is seen an apple which was still quite sound.

Mummied Apples and Methods of Overwintering.—Those diseased apples which become attached to the tree usually remain in that position throughout the winter, becoming dry and shrivelled, and they constitute the so-called "mummied" apples. Many of the spores on the pustules of these "mummies" are washed away by rain or dispersed by the wind in winter; others remain on the pustules, but these usually lose their power of germination. As summer approaches, however, the "mummies" produce a new crop of spores and these cause infection of the young fruit. A "mummy" frequently infects the growing apples directly by contact, but in any case apples in the neighbourhood of a "mummy" are liable to spore-infection through wounds, and such newly-infected fruit will soon produce myriads of spores which serve to spread the disease. The spores are minute in size (only about $\frac{1}{1200}$ in. in length) and are easily dispersed by the wind; insects, too, crawling over the fruit may not only carry the spores from one apple to another, but biting insects, such as wasps, also produce wounds enabling the spores to reach the exposed flesh of the apple where they grow rapidly and reproduce the rot.

FIG. 1.—A cluster of apples (variety, Warner's King) attacked by *Monilia fructigena*.

FIG. 2.—Fruiting spur, from a tree of the Lord Derby variety, bearing pustules of the fungus.

FIG. 3.—An apple (variety, Gladstone) obtained from the store ; it had become black owing to infection by *Monilia fructigena*.

Spur Canker.—On some soft-wooded varieties of apples (e.g., Lord Derby and James Grieve) it has been observed that the disease may extend along the stalk of the affected fruit and into the fruiting spur, or even as far as the branch itself, producing in the latter a canker round the base of the spur. In this capacity of forming cankers it resembles the "Blossom Wilt and Canker Disease" of apple trees caused by a closely-related fungus (i.e., *Monilia cinerea*, Bon.), and already described in this *Journal*.* The two diseases are, however, quite distinct. In the case of the "Blossom Wilt," infection occurs through the open flower, while in the disease described in the present article infection takes place, so far as is known, only through the fruit. Fig. 2 shows the pustules of *Monilia fructigena* occurring on a fruiting spur of a Lord Derby apple tree; the apple in which the infection had arisen had fallen to the ground.

Control Measures.—From the preceding remarks it will be seen that the mummied fruits which are allowed to remain on the trees throughout the winter are the source of the new infection of the growing and ripening apples, and that the one certain preventive measure against the disease is the removal of the affected fruit from the trees. In gardens, allotments and small orchards it is possible to examine the trees at frequent intervals and any apple showing a brown rot, even in an early stage of development, should be promptly removed. On large fruit farms such a course would in most cases be impracticable, but the diseased apples should be removed as soon as possible. This operation might be carried out at the time of picking the crop, the diseased apples being gathered and destroyed, or if that is impracticable they may be dropped to the ground, where they are less dangerous than if left hanging on the tree.

It is advisable, where at all possible, to collect the affected fruit and remove it from the orchard or burn it; in plantations, where the ground is cultivated, such fruit should be dug into the ground. In any case it is imperative that none should be allowed to remain on the trees over winter.

Any affected spurs should be removed, together with cankers on the stem. This operation is best carried out in summer, but it may be done in winter provided it is completed before the fungus resumes its growth in spring.

* Vol. XXIV., No. 5, August 1917.

A Leaflet (No. 312) on "The Blossom Wilt and Canker Disease of Apple Trees" may be obtained free of charge and post free from the Board.

THE DISEASE ON STORED APPLES.—Apples are attacked by the disease not only while still growing on the tree, but also after they are picked and stored. At the time of storing they should be carefully examined and all those showing any trace of the rot should be discarded, for the disease will not only continue to develop in affected individuals, but may also extend to those around them. For the same reason great care should be taken when apples are selected for transmission to a distance in boxes; serious losses have occurred in boxed apples owing to neglect of these precautions.

An experiment carried out on apples after they were picked showed the rot developed in these at approximately the same rate as in the growing fruit, under conditions comparable with those under which apples are stored. Three apples (variety, Bramley's Seedling) were inoculated from pure cultures of *Monilia fructigena* and kept at the ordinary temperature of the laboratory throughout the experiment. At the end of eight days the rot had made considerable progress, as shown by a brown area about $1\frac{3}{4}$ in. in diameter on the surface of each apple, extending round the point where the inoculation had been made. The disease continued to develop and all three produced numerous yellow pustules of the fungus, and eventually became much shrunken and wrinkled.

Under certain conditions stored apples affected by *Monilia fructigena* turn black (as observed by Worthington G. Smith as long ago as 1885*), the skin remaining smooth or nearly so for some time and bearing few or no pustules. Although there is often no evidence on the exterior of such apples that a fungus is present, the flesh is permeated by the fungal threads, and particles of the flesh, placed on suitable culture media, give rise to the growth and pustules typical of *Monilia fructigena*; the black condition too, can be induced in the sound mature fruit by infecting them through wounds with this fungus. *Monilia fructigena* has always been isolated from such black apples (both of the cooking and dessert varieties) from the store at Wye College and from other places in Kent, and it has also been obtained by Spinks† from cider apples which have turned black. The precise conditions which cause the fungus to produce a brown rot in some cases and a black rot in others have not yet been determined. A black apple from which *Monilia fructigena* was isolated is shown in Fig. 3.

AN ALLOTMENT IN LEEDS, AND ITS LESSONS.

A. G. RUSTON, B.A., B.Sc.

(*University of Leeds*).

DURING last year some 3,850 allotments, covering a total area of 300 acres, were under cultivation within the borders of the Leeds area. Many of these allotments had to be laid out on land which seemed utterly unsuitable, and in districts the atmosphere of which was so polluted with smoke as apparently to make success almost an impossibility. In spite of these drawbacks, however, the energy and enthusiasm of the allotment holders have given results which have been not only satisfactory but surprising, and in no case has the writer heard of an allotment being an absolute failure.

A large area was laid out in allotments by the Corporation on Woodhouse Moor, less than a mile from the centre of the city. The soil was anything but ideal; the area was acid, barren, open moorland less than 50 years ago; the situation is equally unfavourable as it is well inside the smoke area, while, in addition, the prevailing westerly winds carry over it the smoke from the Burley Valley.

Letter after letter was written to the papers, pointing out the utter futility of attempting to grow crops on Woodhouse Moor, and blaming the Corporation for allowing men to waste their time and strength in endeavouring to do so. Still the men carried on; they bastard-trenched, and limed and manured; and, putting their backs and their hearts into the work, they accomplished the seemingly impossible. One man obtained $3\frac{1}{2}$ stone of onions from a small patch of 8 sq. yd., equal to 13 tons to the acre; a second got 42 lb. of peas from $\frac{1}{4}$ pt. which was sown in 3 double rows each 10 yd. long; a third planted $2\frac{1}{2}$ stone of King Edward potatoes, and lifted 3 cwt. 0 qr. 22 $\frac{1}{2}$ lb.—more than 10 times the quantity planted.

One of the most interesting series of allotments in Leeds was situated in the Shire Oak Road, in the residential suburb of Headingley, some two miles from the centre of the town. These were laid out by Mr. Bedford, the late Lord Mayor of Leeds, in a field adjoining his own house, and lent rent free (with certain minor restrictions) to his friends. The field had simply been used for the grazing of a carriage horse for the previous 24 years while in his possession, and had been laid down to grass for 50 years at least.

The land sloped gently towards the south, and the soil was a rich fibrous loam overlying the millstone grit, and had a lime requirement of about 1 ton to the acre.

The allotments were laid out in plots each 50 yd. by 4 yd., running north and south, and the conditions stipulated by Mr. Bedford were :—

1. That they should be used only for the cultivation of potatoes.
2. That the rows should be run north and south.

These conditions were partly for the sake of uniformity (the plots were not only close to his private residence, but also open to the road) ; partly because he was firmly convinced that there was no crop so economically important at the present time as the potato ; and also because he felt that if the rows ran north and south the plants would get the maximum amount of sunshine.

Most plots were taken by professional men who took the keenest possible interest in them, and kept most careful and accurate records as to the details of cultivation and the actual yields obtained. Three were cultivated by Mr. Bedford himself, one by his gardener, one by a professor in the Leeds University, one by a well-known medical practitioner (who stated that the physical exercise taken on the allotment had enabled him to throw off a bad attack of sciatica), one by a curate in the neighbouring church, one by a local chemist, and one by the tax collector for the Headingley district.

The treatment of the plots varied in almost every individual case, but all the allotment holders took an intelligent interest in their work, and a keen rivalry existed between them.

The Owner's Plot.—Mr. Bedford took off the turf and sold it for potting soil at 6d. per square yard cut, or 5d. uncut. There was about 10 in. of fibrous loam with an open gritty subsoil, and this loam was manured with well-rotted stable manure made from peat moss litter, and a mixture of leaf mould and road sweepings. Half a load of each was applied to each plot of 200 sq. yd., corresponding to a dressing of approximately 15 tons to the acre. It was dug in before the end of March, and the plots were left ridged and ready for planting by the middle of April.

The sets were obtained on 1st March, 1917, from the Manor Farm, Garforth (Experimental Farm of the University of Leeds and Yorkshire Council for Agricultural Education), and consisted of 5 stone of Eclipse, 4 stone of British Queen, 10 stone of Great Scot, and 4 stone of King Edward—all Scotch seed, once grown, which, with the exception of the Great Scot, had been sorted in the ordinary way, and had passed through the 2-in. riddle (but failed to pass through the 1½-in. riddle). The Great Scot seed had been hand sorted, were well on the large side for "sets," and would have stood cutting.

The Eclipse were sprouted in the cool greenhouse, on shelves with full light where the temperature was somewhat irregular—varying from 42°–68° F. The British Queen were sprouted in a well-lighted cellar,

kept uniformly warm by its proximity to the boiler-house used for heating the radiators. Here the temperature all along kept constant between the narrow limits of 50° – 52° F., and healthy, well-developed, greened sprouts of from $\frac{3}{4}$ in. to 1 in. were made. The Great Scot and King Edward were first placed in the summer-house for sprouting, and left there for two weeks. During this time the weather was very severe, the minimum night temperature falling to 34° F., and the maximum day temperature never exceeding 42° F. Two paraffin lamps were therefore kept burning at night, the windows were papered up to keep out the cold, and by this means the temperature was maintained at from 41° – 43° F. As, however, the sprouting was still unsatisfactory the seed was on 6th April transferred to the cellar floor, where, at a temperature of 52° F., the seed soon began to sprout.

The rows were made two feet apart, six rows to each plot, and before planting on 25th April, a dressing of artificials was sprinkled in the trenches. The mixture was made up of 3 parts of bone meal, 5 parts of superphosphate, 2 parts of sulphate of ammonia, and 10 parts of dry boiler flue-dust containing 8 per cent. of potash.

This was applied at the rate of 7 lb. of the mixture per row of 50 yd., or 3 stone per plot of 200 sq. yd., corresponding to an application of

1 $\frac{1}{2}$ cwt. of bone meal	} per acre.
2 $\frac{1}{2}$ „ superphosphate	
1 „ sulphate of ammonia	
3 „ kainit	

After planting the sets, old lime riddlings from a builder's yard were spread on the top of the soil, approximately 1 ton to the three plots. The lime, however, had been overslaked and had set into hard lumps, so that it became incorporated with the soil so slowly that in the following December the soil still had a "lime-requirement" of approximately 10 cwt. per acre.

As the sets were planted 16 in. apart in the rows, an accurate estimate of the average weights of the individual "sets" of the various varieties can readily be obtained :—

Variety.	Weight Planted.	Length Planted.		No. of Potatoes Planted.	No. of Sets per Stone.	Average Weight per Set.
		In Rows.	In Yards.			
1. British Queen	stone. 4	4 $\frac{1}{2}$	225	506	126	oz. 1.8
2. Eclipse ..	5	5 $\frac{1}{2}$	275	619	124	1.8
3. King Edward	4	5	250	562	141	1.6
4. Great Scot	4	3	150	338	84	2.7

It will be seen that the sets of the British Queen and Eclipse were quite normal, the King Edwards distinctly on the small size, and the Great Scot unnecessarily large.

On 16th May, 21 days after planting, the second early British Queen began to appear above the ground some 8 or 10 days before any signs were seen of the Eclipse; apparently the uniform sprouting of the former at the constant temperature of 52° F. in the well-lighted cellar had had its effects. On 3rd June the British Queen were fine plants, 6–7 in. high, the Eclipse averaged 4–5 in., and the Great Scot and King Edwards 2–3 in. The King Edwards were very irregular, many blank spaces showing, whereas the Great Scot were well up all along the rows.

On 30th June a knapsack sprayer was used to spray all the plots with Burgundy mixture, made up by dissolving $9\frac{1}{2}$ oz. of powdered copper sulphate in 2 gal. of water, and $11\frac{1}{2}$ oz. of washing soda separately in 2 gal. water, and mixing the two together so as to give 4 gal.; $2\frac{1}{2}$ gal. of the mixture were allowed for each plot of 200 sq. yd., a sufficient quantity being made up in a 35-gal. cask for spraying all the plots. The whole of the chemicals required for all the plots were kindly provided free by Mr. Bedford. Spraying was carried out in the cool of the evening, the solutions being first well mixed and tested as to neutrality to litmus. Half a row of Eclipse was left unsprayed as a control.

Up to this time no sign of blight had been noticed, nor, indeed, was there any sign of disease, even on the half row unsprayed, when the tubers were lifted on 15th September. While, however, the tops of the unsprayed lot commenced to go yellow and to fall by about 1st August, the rows which had been sprayed remained green for at least a fortnight later. On finally lifting and weighing the crop it was found that the half row unsprayed yielded 4 stone 6 lb., while the five rows sprayed yielded 55 stone 8 lb. In other words the portion sprayed yielded at the rate of 9.99 tons per acre, and the unsprayed yielded 7.98 tons per acre, the increased yield of the former of approximately 2 tons to the acre being presumably due to the spraying.

On 2nd July the King Edwards were looking distinctly unsatisfactory, and a good number of cases of leaf-curl were noticed. Although late in the season a top dressing of sulphate of ammonia was suggested. Accordingly $\frac{1}{2}$ oz. was sprinkled on the surface of the soil within a radius of 6 in. round each stem, care being taken not to allow it to come within actual contact. This would correspond to a dressing of approximately $2\frac{1}{2}$ cwt. per acre. With the object of testing the result of the application of this top dressing, four rows only of the King Edwards were so treated, the remaining one being left untreated. Up to the time of application of the sulphate of ammonia little or no rain had fallen for more than a month, and the soil was loose and dry to a depth of 9-10 in. Accordingly all five rows were well watered with the hose pipe, which damped the soil to a depth of at least $1\frac{1}{2}$ in., and gave the sulphate of ammonia an opportunity of getting into solution. A break in the weather, accompanied by heavy rains, occurred on 17th July. A great improvement in the appearance of the treated plants was soon noticed, and this improvement was clearly shown in the increased yield on lifting. The one row, not treated, yielded 7 stone 10 lb. (= 6.99 tons per acre), and the four rows receiving the top dressing yielded 39 stone 4 lb. (= approximately 9 tons to the acre).

The following table summarises Mr. Bedford's final results :—

Variety.	Weight Planted.	Area Planted in Sq. Yd.	Actual Yield.	Yield per Acre.	Increase in Terms of Seed Planted.	Date Lifted.
1. British Queen	stone. 4	sq. yd. 150	stone. 42	tons. 8.47	10.5 fold	26 Sept.
2. Eclipse ..	5	184	60	9.88	12.0 "	15 "
3. King Edward	4	166	47	8.41	11.8 "	5 Oct.
4. Great Scot ..	4	100	25	7.56	6.2 "	10 "
Total or Average	17	600	174	8.58	10.1 fold	

The Professor's Plot.—Professor Barker bastard-trenched his plot, burying the turf, and adding three loads of horse manure and one load of cow manure. The loads were small, probably 15 cwt. each, but a total dressing of 3 tons to the plot was decidedly heavy, equal to about 72 tons per acre. The digging was started in December, 1916, and finished in April, 1917. Seven varieties of sets were obtained—half a stone of each variety. These arrived at the end of April, and were not sprouted. They were planted in rows 2 ft. apart, and 12 in. apart in the row. The plot, therefore, contained 6 rows, each 50 yd. long. As the $3\frac{1}{2}$ stone of sets were not sufficient to plant the plot, additional sets were obtained, part from the Leeds market and part from a Headingley greengrocer. In each case the sets were simply small potatoes picked from samples of eating potatoes of unknown pedigree and history.

The following summary of Professor Barker's results is certainly interesting and instructive :—

Variety.	Seed Obtained from	Weight Sown.	Yards Sown.	No. of Sets per Stone.	Average Weight per Set.	Total Yield.	Yield in Tons per Acre.	Increase in Terms of Seed Planted.
		lb.			oz.	lb.	tons.

The Doctor's Plot.—Doctor Mayo bastard-trenched his plot, burying the sod face downwards and chopping it up into very small pieces, and applied 3 loads of stable manure to the plot of 200 sq. yd. The cultivation of the plot was started on 26th December, 1916, and completed on 24th March, 1917. The sets were all sprouted in boxes, the earlies were planted on 19th April, and all the sets were in by the first week in May. The sets were obtained from a local nurseryman who stated that the Arran Chief were Scotch seed and that the others had been grown in Lincolnshire. The Eclipse and Sharpe's Express were planted thickly in rows 18 in. apart, and the sets 12 in. apart in the rows; the British Queen and Arran Chief in rows 2 ft. apart, and the sets 12 in. apart in the rows.

A proportion of the potatoes grown was slightly holed by wire-worms, but very few so badly that they had to be given to pigs. A small number, mainly the Arran Chief, were also attacked by black slugs. With the exception of $7\frac{1}{2}$ lb. of potatoes, mainly sound, but too small for cooking which were consequently given to pigs, all the produce from the plot has been actually consumed by the household.

The following is a summary of the results on Dr. Mayo's plot:—

Variety.	Weight Planted.	Weight Lifted.	Increase in Terms of Seed Planted.	Yield per Acre.	Average Weight Per Root.
1. Eclipse	lb. 23	lb. 187½	8·1 fold	tons. 11·04	oz. 14·38
2. Sharpe's Express ..	10	70½	7·0 "	9·20	12·4
3. British Queen ..	36	331½	9·2 "	10·29	17·3
4. Arran Chief ..	40	321	8·0 "	10·60	20·4
Total or Average	109	910½	8·1 fold	10·28	

It is an important economic fact that the eight plots (approximately a third of an acre—part of a field which up to last year had done nothing for 50 years except to find food for a pleasure horse) produced altogether 3 tons 16 cwt. of potatoes, sufficient to provide *three men with their daily requirements of 3,400 calories for one year.*

It was ascertained that:—

(1) It is more economical to give a medium dressing of dung and supplement with artificials than to give excessively heavy dressings of dung alone. Thus Mr. Bedford, who sold the turf and applied only 15 tons of dung per acre, supplementing with artificials, got a return of 9 tons of potatoes per acre; Dr. Mayo, who in addition to burying the turf gave the heavy dressing of 57 tons of dung per acre, only got a return of 10 tons per acre, or one ton more than Mr. Bedford; and Professor Barker, who in addition to burying the turf gave the excessive dressing of 72 tons of dung per acre, obtained a return of 11 tons. Mr. Bedford's potatoes were produced at the cheapest rate.

(2) It undoubtedly pays to get seed potatoes from a reliable firm—if possible Scotch seed direct from Scotland or, failing that, Scotch seed once grown in the district. Thus Professor Barker's Up-to-Dates, obtained from a reliable firm, yielded 20·5 tons to the acre, and the same variety picked up casually only yielded 3·6 tons; his King Edwards, obtained from a reliable firm, yielded 11·4 tons to the acre, and those picked up in the market only 3·4 tons; his Eclipse, from a reliable firm, yielded 9·2 tons to the acre, and those obtained from the market only 6·4 tons. To go to the trouble of bastard-trenching and to the expense of manuring with dung at the rate of 72 tons to the acre, and then to plant nondescript sets, picked up casually, is to court disaster and to waste both energy and money.

(3) *It certainly pays to spray potatoes*, as it not only checks and prevents blight, but prolongs the growth of the plant, and tends to give an increased yield. The portion sprayed on one of Mr. Bedford's plots gave an increased yield of approximately 2 tons to the acre, as compared with a similar portion on the same plot which had not been sprayed.

(4) If the land is in need of lime, as is probably the case with most land in the neighbourhood of an industrial town, the lime applied must be *in a fine state of division* if it is to become incorporated with the soil. The soil on Mr. Bedford's allotment had a lime "requirement" of 1 ton to the acre. Mr. Bedford applied a dressing of 8 tons to the acre, using lime that had been overslaked and had set into large lumps; and the soil still had a "lime requirement" of $\frac{1}{2}$ ton to the acre.

(5) When plants are flagging from drought, a *top dressing of sulphate of ammonia* will usually help them along, even when applied as late in the season as the end of June, *provided that the conditions are such that the sulphate of ammonia can get into solution in the soil.*

REPORT OF THE TITHE, COPYHOLD, COMMONS, AND SURVEY BRANCH OF THE BOARD FOR THE YEAR 1917.*

THE Report for the year 1917, on the Proceedings by the Board under the Tithe, Copyhold, Inclosure and other Acts, administered through the Tithe, Copyhold, Commons, and Survey Branch of the Board, deals chiefly with the question of tithe rentcharge.

TITHE ACTS, 1836 TO 1891.—The oldest of the duties with which the Board are charged are those arising from the administration of the Acts relating to tithe rentcharge and other payments in lieu of tithes in kind. Generally speaking tithes may be described as the tenth part of the annual increase arising from the lands and the stock upon the lands. With certain exceptions tithes were payable on common right in respect of the produce of all lands which were not barren.

The practice of taking tithes in kind continued for several centuries, but in many respects this mode of payment was inconvenient to both the receiver and the payer of the tithe. Accordingly, in many parishes the practice arose of

* The usual Annual Reports of the various Branches of the Board are not at present issued separately.

compounding for tithes by payments called *moduses*, a *modus* being a composition made between the parson, patron, ordinary and landowners before the time of legal memory, *i.e.*, before the year 1189, whereby the landowners agreed to pay the parson for the time being for ever a certain sum of money or other thing in lieu of tithe.

An objection to a money *modus* was that any fixed money payment is necessarily liable to great fluctuations in purchasing power. For instance, a very common *modus* was 2*d.* an acre in lieu of the tithes of the produce of the lands, and it may reasonably be assumed that this sum was the full value of the tithes when the *modus* originated, *i.e.*, before the year 1189; but it has been estimated that at the time of the general commutation in 1836 the average value of the tithes in kind of an acre of land was about 4*s.* Thus, in the course of centuries the effective value of a *modus* had been depreciated to about one twenty-fourth part of what it was in the twelfth century.

The expedient of substituting corn, which is not liable to the same depreciation as money, was adopted as regards college leases by the Statute 18 Eliz. c. 6, which directed that one-third of the old rent, then paid, should for the future be reserved in wheat or malt, reserving a quarter of wheat for each 6*s.* 8*d.*, or a quarter of malt for every 5*s.*, or that the lessees should pay for the same according to the price for which wheat and malt should be sold in the market next adjoining to the respective colleges, on the market day before the rent became due.

"It has been said that this was an invention of Lord Treasurer Burleigh, and Sir Thomas Smith, then principal Secretary of State, who, observing how greatly the value of money had sunk, and the price of all provisions risen, by the quantity of bullion imported from the new-found Indies (which effects were likely to increase to a greater degree), devised this method for upholding the revenues of colleges. Their foresight and penetration has in this respect been very apparent; for, though the rent so reserved in corn was at first but one-third of the old rent, or half of what was still reserved in money, yet now the portion is nearly inverted; and the money arising from corn rents is, *communibus annis*, almost double to the rents reserved in money." (*Blackstone's Commentaries on The Laws of England*, 21st Ed., Vol. II., p. 322.)

During the century preceding the passing of the Tithe Act, 1836, about 2,230 local Inclosure and other local Acts were passed, in which provision was made for the commutation of

the tithe, in some cases of the lands to be inclosed, and in some of the whole parish. In order, no doubt, to avoid to some extent the fluctuations in purchasing power to which fixed money payments are liable, some of the money payments created under these Acts were calculated on a certain price of corn, and were made subject to variation, on application to Quarter Sessions at specified intervals of years, on the basis of the increase or decrease in the average price of corn during a specified period previous to the variation.

The Tithe Act of 1836, which provided for the commutation of all the remaining tithes in England and Wales into tithe rentcharge, directed that every tithe rentcharge, at the time of the confirmation of the Tithe Apportionment, should be deemed to be of the value of such quantities of wheat, barley and oats as the sum would purchase in case one-third part thereof were laid out in wheat, another third part in barley, and the remaining third part in oats at the average prices for the seven years ended Christmas, 1835. The Act further provided that after every first day of January, the sum of money payable in respect of the rentcharge should vary so as always to consist of the price of the same quantities of wheat, barley and oats, respectively, according to the average prices for the seven years ended the next preceding Christmas.

Eighty-two years have now elapsed since the Act of 1836 was passed. During the earlier part of this period the annual variations were on the whole favourable to the receiver of the rentcharge, but in recent years they have greatly favoured the payer of the charge. In 31 of the 47 years from 1837 to 1883 inclusive, the value of tithe rentcharge exceeded par, but in every year since 1883 the value had been below par until the present year, when it stands at £109 3s. 11d. for each £100 of tithe rentcharge. This last-mentioned value represents an increase of £17 2s. 10½d. on the previous year's figure, and is only £3 11s. 7½d. less than that for 1875, when tithe rentcharge reached its highest level.

Now that, after the lapse of many years, the variations in the value of the charge seem likely again to operate in favour of the tithe-owner for some years to come, the Board have received many representations from various bodies and individual landowners to the effect that tithe rentcharge should be fixed either at par or at some amount below the par value of the charge. Landowners seem generally to admit that, in increasing with the price of corn, tithe rentcharge is merely doing what the Legislature intended that it should do, but they urge that the

increase in corn prices is largely due to the "U" boats and other factors which were quite outside the contemplation of the parties to the statutory bargain made in 1836. In this connection it may be interesting to recall that the Royal Commission on Agriculture, 1879, recommended that tithe rentcharge should be fixed and invariable, and that tithe rentcharge charged on property in the City of London under the London (City) Tithes Act, 1879, and the 4 per cent. rentcharge payable under the Extraordinary Tithe Act, 1886, are not subject to variation.

The effect of the Corn Production Act, 1917, on the value of tithe rentcharge is often misunderstood. The amount payable under the Tithe Acts in respect of any tithe rentcharge varies from year to year in accordance with the average market prices of wheat, barley, and oats for the seven preceding years, as published in the "London Gazette," and these prices will not be affected by the provision in the Corn Production Act securing certain payments to the grower, where the year's price of either wheat or oats, determined as prescribed by the Act, falls below the "minimum" price specified in the Act.

There is nothing in the Act to prevent a landowner from obtaining an increased rent to cover his increased outgoings, including tithe rentcharge, provided that the effect of the guaranteed prices is left out of the account; and, in view of the market prices which now rule for wheat and oats and the probable market prices for the next few years, the influence of the guaranteed prices on rents is in any case likely to be very slight indeed.

It is frequently suggested that the best solution of the problem resulting from the rapid increase in the value of tithe rentcharge is to provide greater facilities for redemption. The existing provisions for the redemption of tithe rentcharge are contained in the Tithe Acts, 1846, 1860 and 1878, and may be summarised as follows:—

- (a) When the land has been taken for places of worship, cemeteries, schools under the Elementary Education Acts, town-halls, court-houses, gaols, lunatic asylums, hospitals, or any other public buildings, or under the Housing of the Working Classes Act, 1890; or for sewage farms under the Sanitary Acts, or for the construction of any sewers or sewage works, or any gas or waterworks, or for enlarging or improving premises used for any of the above-mentioned purposes, the Tithe Act, 1878, requires that the rentcharges shall be redeemed; and the application is to be made by the persons in possession of the land before the land is applied to any of the purposes aforesaid, the rentcharge being redeemable for 25 times the amount thereof.

- (b) When the land is charged with a rentcharge not exceeding 20s., application for redemption may be made by the landowner, or by the owner of the tithe rentcharge, and the rentcharge is redeemable, if the Board see fit, for 25 times its amount.
- (c) When the land is charged with a rentcharge exceeding 20s., the rentcharge may be redeemed on the joint application of the owner of the land and the owner of the tithe rentcharge for a sum not less than 25 times its amount; but when the rentcharge is held in right of a benefice, the consents of bishop and patron are also necessary, and may be signified on the application.
- (d) When the land has been divided since the last apportionment into numerous plots for building or other purposes, so that no further apportionment can conveniently be made, the application may be made by the owner of any of the plots, or by the owner of the tithe rentcharge, and the rentcharge is redeemable for 25 times its amount. An application made by a landowner must not include any number on the tithe map which has a separate rentcharge, unless he owns part of the land to which it refers.

In all cases the basis of redemption is the amount set out in the tithe apportionment, and not the varying value according to the corn averages from year to year.

It is often overlooked that in certain circumstances tithe rentcharge may be extinguished by a declaration of merger as an alternative to redemption. The consideration for merger is a matter for arrangement between the landowner and the titheowner, the fee payable to the Board is less than in the case of redemption, and declarations of merger are not subject to stamp duty. The following persons may execute a declaration of merger:—

- (a) A titheowner who is entitled to the rentcharge in fee simple or fee tail in possession, or has the power of disposing of the fee simple in possession therein, although he does not also own the land charged therewith.
- (b) A titheowner who is entitled to the rentcharge as tenant for life, provided that he owns also the land charged with the rentcharge, and that both the rentcharge and the land are settled to the same uses.

A tenant for life who does not also own the land can, as a rule, with his trustees and the owner of the land, execute a bargain and sale to the intent that the rentcharge shall merge in the land.

- (c) A person entitled in equity to tithe rentcharge may execute a declaration of merger in all respects as if he were legally entitled thereto.
- (d) A clerical incumbent entitled in virtue of his benefice to tithe rentcharge charged on glebe lands of his benefice can merge the rentcharge in the land.

Out of an original total of £4,054,405 of tithe rentcharge apportioned on lands in this country under the Tithe Acts

only £72,513 has been redeemed, and £156,866 merged. Extraordinary tithe rentcharge, the amount of which at the commutation cannot be accurately stated, has been converted under the Extraordinary Tithe Redemption Act, 1886, into the 4 per cent. rentcharge provided for by that Act, while a certain amount of ordinary tithe rentcharge has been extinguished in exchange for land under the provisions of the earlier Tithe Acts. On the other hand, variable corn rents have been converted into tithe rentcharge amounting in all to £6,921 under the Tithe Act, 1860. Making due allowance for all these transactions the total amount of tithe rentcharge now payable is £3,678,675, so that in the course of 82 years the provisions for extinguishment have resulted in a diminution of the total charge by 9 per cent. At this rate it will, under existing legislation, take over 800 years to complete the extinguishment of tithe rentcharge in this country.

This slow rate of extinguishment is no doubt chiefly owing to the fact that the conditions under which tithe rentcharge may be redeemed have, for many years past, been unduly favourable to the titheowner, and correspondingly unfavourable to the landowner. Allowing 5 per cent. for collection and rates at 5s. in the £, an assessable value of, say, £76, equal to £19 full rates and £9 10s. half rates, the net value of tithe rentcharge to the lay impropiator would be:—

Present value of tithe rentcharge	£	s.	d.
.. .. .	109	3	11
Less cost of collection	£	s.	d.
.. .. .	5	9	2
„ full rates	19	0	0
	<hr/>		
		24	9 2
Value to the impropiator	£	84	14 9

[On the other hand, the value to the incumbent, who, under the Tithe Rentcharge (Rates) Act, 1899, pays half rates only, would be £9 10s. more, namely, £94 4s. 9d. As compared with this sum, the income derived by the incumbent after redemption at 25 years' purchase would be 5 per cent. on £2,500, that is £125, and such income would not be subject to rates. The landowner would be relieved of the full amount of the charge, £109 3s. 11d., but the land would be liable to re-assessment for rating purposes, and in these circumstances redemption at the present time offers but little attraction to the landowner as an investment.

It is obvious that, if redemption is to be made more popular, drastic alterations in the terms under which redemption may be effected must be made, and that any proposals which would involve an increase in the official fees or in other expenses of, or incidental to, redemption must be avoided. It may be of interest to note that in the Report of the Royal Commission on Redemption of Tithe Rentcharge, 1892, it was recommended, *inter alia*, that "the existing terms of 25 years' purchase of commutation value for the redemption of tithe rentcharge should be abolished; that where redemption is voluntary the precedent of the Glebe Lands Act, 1888, should be followed, and the parties be encouraged to make their own bargains, subject to a determining authority as to the price of redemption to be vested in the Board of Agriculture; that in the case of clerical rentcharges a notice to the bishop and patron should be substituted for the present provision which requires their consents in certain cases; and that where redemption is compulsory the terms should be fixed by the Board of Agriculture."

The Commission further recommended that the fees payable should be reduced and, if possible, abolished in the case of small rentcharges. They also suggested that any legislation for facilitating the redemption of tithe rentcharge should be made applicable, with suitable modifications, to corn rents and other payments in lieu of tithe arising under local Acts of Parliament. Many such Acts provide that the payments which they impose shall not be subject to rates and taxes, and this fact should apparently be taken into consideration in any revision of the terms under which the payments can be redeemed.

There are no available statistics showing the proportions of the tithe rentcharge now payable which are owned by parochial incumbents and other classes of titheowners respectively. The following statement, however, shows the proportions at the time of the commutation:—

Owners.	Tithe Rentcharge.
Parochial incumbents	£ 2,412,104
Lay appropriators	766,206
Clerical appropriators and their lessees	680,037
Schools, colleges, etc.	196,056
Total	£4,054,405

Since the commutation there have been numerous dealings with tithe rentcharge. A considerable amount of inappropriate and appropriate tithe rentcharge is held by the Ecclesiastical Commissioners, and a great deal has been annexed to various benefices either through the Ecclesiastical Commissioners or by direct gift. Many colleges, hospitals and other charities own tithe rentcharge, while some is held by municipal bodies, such as the Corporations of Coventry and Bury St. Edmunds, respectively.

THE Board have received from the Agricultural and Horticultural Research Station (National Fruit and Cider Institute), Long Ashton, Bristol, a copy of

**Investigations
at the National
Fruit and Cider
Institute.**

the Research and Advisory Report of the Station for the year ended 30th September, 1917. Owing to the prolongation of the War and the consequent need for the concentration of all effort on work of immediate national importance, and also to the reduction of the scientific staff, the ordinary research and experimental work has been reduced to the smallest possible proportions, and the land is being cultivated in the interests of national food production.

Courses of training in fruit culture for partially disabled officers to last over a period of 2 years have been arranged at the request of the Board of Agriculture and the Ministry of Pensions.

The following is a summary of the main work of the Station during the year under review :—

Stock Influence on Fruit Trees.—The apple root stock investigations which have been for some years jointly conducted at the East Malling Fruit Station and Long Ashton have now reached a point where the first stage of the work can be considered to be complete.

At East Malling the classification of the various types of Paradise root stocks in use in the fruit nurseries of this country and, to a less degree, in France, Holland and Germany, has been thoroughly worked out, and an exhaustive report on the individual types has been recently published. Each type is being propagated extensively with a view to the organisation of extensive comparative trials at suitable centres, and it is expected that the first supplies will be budded with the selected test varieties during the year 1918.

At Long Ashton sufficient information as to the various types of root system occurring among free and crab stocks has

been gained to permit of the grading of individual stocks into more or less well-defined classes, and selected plants representing each class are being propagated as rapidly as the character of the individuals will permit. When sufficient supplies are available comparative trials of the same kind as those arranged for the Paradise types will be started.

Fruit Bud Formation.—The observations on fruit bud formation, begun in 1916, have resulted in the accumulation of many data tending to throw light upon the causes which determine the line of development of the individual bud, whether into the vegetative type or into the fruit bud. It is already evident that many factors are involved, and that, given the necessary knowledge of the action of individual factors, a considerable degree of control over the potential crop for the following season could be attained by suitable treatment of the tree during the growing period of the year, particularly during the latter half of the growing season. The practice of summer pruning is the means of effecting this control adopted by fruit growers, but the variability in the results of the treatment is sufficient indication that the method as ordinarily practised is limited in its usefulness on account of the absence of precise knowledge of the conditions which should be taken into consideration. The variations in the response of individual trees under different conditions to summer pruning, which have been observed in the course of the experimental work on this subject, have served to throw considerable light upon the factors involved and the respective courses of action necessary to suit prevailing conditions. Several sets of experiments to test individual points have been started.

Spot Disease of Apples.—Investigations were made on the origin and development of spots which occur on apples in store. These spots were found to be caused by various fungi, but the real source of the trouble appears to be some physiological effect which produces weak places in the cuticle of the apple through which the fungi can obtain an entrance. Attempts are now being started to discover conditions of storage which will prevent the fungi from entering the apples and will also prevent their extensive growth even if they enter.

Further Studies on the Fruit Blossom Bacillus.—This organism, which was discovered in 1913 at Long Ashton to cause a serious disease of fruit blossom and of flower buds, especially in the case of pears, has been further studied during the succeeding years, and several new facts as to the disease have been observed.

The characters of the organism have recently been determined in considerable detail, partly on account of the discovery of a somewhat similar form in South Africa which causes a fruit blossom disease there, and partly owing to the discovery of the existence of an apparently identical form in considerable numbers in soil. The latter fact was observed soon after the disease was first investigated at Long Ashton; but the more recent observations that the bacillus occurred in large numbers in close association with the fine roots of growing plants, and that the quantity in portions of the soil not permeated by roots was insignificant, added considerable interest. A careful comparison of the root form and the blossom form has proved that the two are probably identical, the difference between individual cultures being extremely minute. In view of the fact that the organism produces ammonia readily from proteid nitrogen and other organic nitrogenous substances, its effect on seedlings and growing plants was tested. In unsterilised soil in open ground the watering of the roots with a vigorous culture of the bacteria gave no positive result, but in the case of seedlings in sterilised soil a definite stimulus to growth was observed in some of the experiments. The negative result in unsterilised soil may be due to the natural presence of the organism in adequate numbers. Further experiments are necessary before definite conclusions are drawn as to the significance of the organism in the soil.

Further Experiments on the Rhizootonia Disease of Asparagus.—

The experiments on the infected land at Badsey which were begun in 1916 have been continued with a few minor modifications. The 1916 results showed that treatment of the soil with carbolic acid or naphthalene offered little promise of success. Accordingly the plots originally treated with those substances were in the 1917 trials dressed with bleaching powder and creosote respectively, those substances having in the previous season had most effect. The other plots were dealt with as in 1916. The test crop grown was again carrots. The results corresponded generally with those obtained in 1916, the control plots being full of disease and the remainder showing a limited quantity only, the amount varying according to the nature of the fungicide applied. Bleaching powder and creosote again stand out as distinctly the most efficient fungicides, the former especially producing striking results. On the plot which has now been treated with it for two consecutive seasons, the disease appears to have been practically eliminated and the crop has not been adversely affected in other ways.

It now seems worth testing the effect of bleaching powder and certain other chlorine-containing preparations on other types of pathogenic soil fungi, the forms of treatment hitherto in vogue being very unsatisfactory. An extension of the experiments at Badsey on a larger scale is being arranged for 1918.

Big Bud Disease of Black Currants.—During the winter further work on this disease was done. Diseased bushes were sprayed during the dormant season with the carbolic-soft soap wash previously found the most successful of all the mixtures used. The effect of one and two sprayings at three different periods was tried. In the most successful combination the number of living and checked big buds was reduced to 16 per cent., 84 per cent. being completely killed.

"Reversion" in Black Currants.—Work described in a previous report led to the conclusion that any injury to the terminal bud of a shoot was liable to lead to reversion. Considerable light has been thrown on the problem through examination of some material kindly sent by Messrs. Seabrook and Sons. Shoots from "Seabrook's Black," a mite-resistant variety, showed interesting and characteristic small buds when examined in winter. The growing point of these buds had been killed, presumably by mite attack during the summer. The resistance offered to mite attack was apparently due to this fact, although several subsidiary factors also affected the case.

Reverted wood was found to be caused by the normal terminal bud being replaced by a small "killed" bud, a "blind" bud, a "big" bud, or a fruit bud. All would produce a distinct check to normal apical growth in the spring and cause undue growth of the lateral buds, a condition always associated with reversion. These causes account for the greater number of cases of reversion found amongst commercial plantations. There is, however, one kind of reversion, the cause of which is still obscure. This is being investigated at Long Ashton.

Raspberry and Loganberry Beetle (*Byturus tomentosus*).—From previous laboratory experiments it had been found that the killing power of dilute nicotine solutions was greatly increased by combining them with paraffin emulsions containing 2 per cent. each of soap and paraffin.

The emulsion acts in this case as a carrier. The combination : Paraffin, 2 gal. ; soft soap, 20 lb. ; nicotine, $\frac{1}{2}$ lb. ; and water, 100 gal., was tried against the loganberry beetle as soon as it appeared on a commercial plantation near Evesham. By a suitable method of spray application the number of infected

berries was reduced from 100 per cent. on the control row to 33 per cent. on the sprayed row.

Copper Stearate Mixtures.—The need for a protective fungicidal spray with better covering and wetting power than is possessed by Bordeaux or Burgundy mixtures led to an investigation of the possibilities of obtaining a mixture containing free soap. For some time difficulties of a chemical nature prevented a solution of the problem, but these have now been overcome. A mixture has been obtained which possesses certain valuable properties. Any amount of wetting power desired can be obtained and the film left after spraying is such that the distance between contiguous particles is far smaller than the diameter of any fungus spore. It may thus be regarded as continuous. It has good adhesive powers and considerable resistant properties to water, and will, therefore, probably stand weather conditions. Its fungicidal properties have not yet been absolutely proved, but the copper is in a form soluble enough to be taken up by bean seedling roots, where characteristic copper blackening was obtained. This indicates that the substance will probably prove fungicidal. Further tests are being carried out.

Cider Vinegar.—One of the results of the War is a shortage of malt vinegar, which seems likely to increase. The possibility of reviving the use of cider vinegar has been considered and a number of inquiries concerning this product have been received. Experimental work in connection with its production is in hand and attention has also been given to its use for pickling purposes. Some practical difficulties which hitherto limited its utility, such as the development of turbidity after pickling, have now been overcome; and as stocks of malt vinegar become further reduced it is possible that cider vinegar may be extensively used. Steps are being taken to carry out trials for its production on a commercial scale.

The Bacteria of Ropy Cider.—While methods of treating ropy cider to make it fit for consumption had been worked out previously, the organism or organisms causing the disorder in English cider had not hitherto been isolated, and therefore investigations on the prevention of ropiness were seriously hampered. Two bacteria capable of causing ropiness have now been successfully isolated from ropy cider as the result of the past season's work, and their characters have been already fairly thoroughly examined. With the information thus gained and from work on the growth conditions of the organism still in progress, the problem of prevention of ropiness should be considerably simplified.

The Utilisation of Pressed Cider Apple Pomace.—Much further work has been done on this subject. The market value of this pomace has risen to from £1 to £2 per ton according to district, and, since the amount of the pomace produced as a by-product in cider-making is $\frac{1}{3}$ to $\frac{1}{4}$ of the total weight of apples used, it represents an asset of some value to the cider maker. Several methods of preserving pomace, suitable for use on farms, are being examined; but the bulk of the supply now being produced is either utilised in its fresh state for stock-feeding or is being distributed to various drying centres. The collection of stocks for the latter purpose is being organised by the Station, and arrangements have been made which will prevent the greater part of the waste which has hitherto occurred.

The experiments on the feeding value of the pomace for pigs, which were begun at Seale-Hayne College in the autumn of 1916, were continued into the New Year so long as supplies of apples and pomace were available. They demonstrated that pomace possesses distinct value as a food. In its dried form it is now being used as a "filler" in place of bran in compound cattle cakes, but it is certainly proved that it must be regarded as something more than that.

Apple Pectins.—The investigation of the chemistry of these substances is being proceeded with, but for the most part attention has been concentrated upon their extraction from pressed apple pomace in a form likely to be of practical use in jam-making. This work has now reached a point where tests under commercial conditions are required, there being now practically no doubt about the possibility of the preparation of a suitable product in a form which will keep sound and retain the necessary "setting" qualities indefinitely.

The Utilisation of Cider Fruit in Food Production.—(a) *For Culinary Purposes.*—The sour or sharp class of cider apples presents no difficulty in this respect and has always been more or less drawn upon when ordinary market varieties have cropped poorly; but the sweet and bitter-sweet classes have always hitherto been regarded as comparatively worthless for the purpose, since the fruit would not cook properly, always remaining hard or only irregularly softened. The work on apple pectins has shown that this was due solely to deficiency of acid, the greater part of the "pectin" in these apples being in a form more or less insoluble in water—even after prolonged cooking at boiling point under ordinary atmospheric pressure—but readily soluble in dilute acid solutions. The addition of

the juice of any sour fruits or of any convenient and non-injurious kind of acid to the fruit during the course of cooking easily and quickly reduces the apples to a perfectly cooked state of pulp, and by this means any sweet or bitter-sweet variety can be used with complete success as a substitute for recognised culinary sorts.

(b) *For Jam-making.*—By the same means apple pulp suitable for use as a basis for jams can easily be prepared from the sweet and bitter-sweet kinds. A thoroughly palatable jam can be made from this pulp alone without the addition of any flavouring material. The method affords a new use for pressed apple pomace. Jam can be made from the latter as readily as from the whole fruit.

(c) *For Jelly-making.*—It was possible to arrange to carry out on a commercial scale during the cider-making season of 1917 a trial of making jelly from cider apple juice according to the method which has been worked out at the Station since the outbreak of war. Two centres were to be equipped for the purpose, one at the Research Station at Long Ashton and the other at Wedmore, near Cheddar. Two forms of evaporator were to be tested, viz., a Kestner evaporator, such as is used for the concentration of sugar syrups, at the former place, and an American type of fruit juice evaporator at the latter. It will be possible to test not only the suitability of these kinds of evaporating machines, but also the financial side of making this article, and to deal with the practical problems involved in working under commercial conditions. The schemes are being organised and financed by the Horticultural Division of the Food Production Department of the Board of Agriculture and Fisheries.

REALISING that one effect of the War might be a shorter supply of cheese, the Board in 1915 formulated a scheme to encourage the conversion of all surplus milk into cheese.

**The Services of the
Co-operative Cheese
Schools in the
Formation of Milk
Depots.**

This scheme was submitted to the several County Education Authorities throughout England and Wales, with the suggestion that wherever circumstances presented reasonable opportunities for the development of the cheese industry, it was desirable that steps should immediately be taken to provide suitable instruction of a practical nature to enable producers to turn all surplus milk to the best account.

As a consequence several County Authorities established travelling cheese schools in the year 1916. Every school so established was fully employed, and the work performed was attended by a considerable measure of success.

The milk used in these schools was usually supplied by those attending for instruction. For the first few days of each class the milk supplied by each individual would be made up separately and the resulting cheese returned to them, but as the work proceeded the suppliers were in several instances induced to pool their milk, so that a large cheese might be made instead of a number of small ones.

This action constituted the first step in co-operation, and soon led to the request for a school to be supplied with a larger set of apparatus, since the supply of milk was greater than the smaller apparatus at first employed could usefully convert into cheese.

The experience thus gained caused the Board to experiment in 1916 with a Co-operative Cheese School, that is, a school equipped with a large set of apparatus and conducted so as to demonstrate the possibility of co-operative action in cheese-making among milk producers.

The results which were attained by this experiment so satisfied the Board that for the season 1917 they prepared a general scheme for the conduct of such schools and laid it before the County Education Authorities for consideration. This scheme provided that where the milk producers in the district would undertake (1) to supply a minimum quantity of milk per day (usually about 200 gal.) for the duration of the school; (2) to accept payment for such milk on a strictly co-operative basis; and (3) to appoint and place under the charge of the instructress during the period of the school some approved person whom they intended to become their manageress in the event of their carrying on the undertaking of cheese-making on a co-operative basis, after the school is finished, the County Authority should provide a set of apparatus sufficient for the purpose of the school and should supply the services of an instructress.

The scheme provided that the duration of a school at a centre should usually be from 2 to 3 months, but stated that it was important that before withdrawing a school from any centre the Authority should be satisfied that the people of the district had been thoroughly instructed in cheese-making, that the person intended to become the manager of the Co-operative Cheese Factory (assuming that the cheese factory had been

decided upon) had become reasonably competent, and that, so far as possible, all local difficulties had been overcome and that a thorough demonstration in co-operation had been afforded.

Seven County Education Authorities adopted the scheme, with the result that there were conducted in 1917 nine co-operative cheese schools—2 in Cornwall, 1 in Wiltshire, 2 in Herefordshire, 1 in Montgomeryshire, 1 in Cheshire, 1 in Denbighshire, and 1 in Carnarvonshire. These schools worked throughout the season and were in every case successful. The producers supplying the several centres were fully satisfied with the returns obtained, and a true spirit of co-operation was engendered—as is shown by the fact that the demonstrations thus provided have resulted in the establishment of 8 new co-operative societies which are this year conducting duly registered co-operative dairy factories, some of them on a considerable scale.

In the autumn of 1917 the Committee on Production and Distribution of Milk recommended, in their Second Interim Report, that steps should be taken to establish milk depots in districts where milk is produced in considerable quantities, but which through lack of organisation does not ordinarily become available for human consumption; and in order to facilitate the creation of such depots, they advised that the State should, if necessary, assist by lending a portion of the capital required.

The Board of Agriculture took action on this recommendation and obtained the sanction of His Majesty's Treasury to lend capital, on the basis of 6 per cent. interest, and repayable in a definite term of years. A general scheme was devised for the purpose, and the work of organising the depots was placed with the Agricultural Organisation Society.

Already 8 new depots have been established under this scheme and others are in process of formation. It is interesting to note that of these 8 depots, 5 are located where co-operative cheese schools, conducted in accordance with the Board's scheme, were held last season.

The work of the co-operative cheese schools last season has led to a greatly increased demand for such schools to be conducted this year. Already there are in operation 3 in Cornwall, 1 in Wiltshire, 1 in Berkshire, 2 in Herefordshire, 1 in Montgomeryshire, 1 in Cheshire, 1 in Flintshire, 2 in Denbighshire, 2 in Anglesey, 1 in Carnarvonshire, and 2 in Cumberland.

SEVERAL varieties of cheese can be made with buttermilk, either used alone or added in certain proportions to new milk or skim milk.

Buttermilk Cheese.

(1) To make a soft cheese from buttermilk alone the buttermilk must be heated to a very high temperature, since, being sour, it is not coagulated by rennet. In making this class of cheese the buttermilk must be *sour*, and the produce of thin cream, *i.e.*, cream yielding 3 lb. to 4 lb. of butter per gal. Should the cream have been taken off very thick by the cream separator, the caseous matter is found in suspension after heating and cannot be separated from the whey.

Buttermilk should be sour or acid, but as freshly made as possible. If sweet it may be necessary to use a starter to sour it before attempting to make it into cheese. In the small dairy buttermilk should be used for cheese-making as early as possible after it has been drawn from the churn, and it should be as pure—*i.e.*, mixed with as little rinsing water—as possible. The buttermilk should be placed in a clean pail and heated by immersion in a copper of hot water to about 160° Fahr. As the contents of the pail get hot, the curd will gradually separate. When a temperature of 160° Fahr. has been reached, the pail and its contents should be placed on one side and covered up for about an hour. This allows of the curd collecting into a mass. When this stage is reached the curd should be strained. This is done by spreading a piece of clean cloth over a frame provided with a rack or with a bottom made of galvanised wire netting of $\frac{1}{2}$ -in. mesh, with three $\frac{3}{4}$ -in. slats nailed lengthwise underneath to clear the draining table. The curd should be scraped down occasionally and finally pressed with a board, weighted with a brick until the curd is dry enough to make up. It may then be salted to taste and made up into $\frac{1}{4}$ -lb. or $\frac{1}{2}$ -lb. sizes, similar in shape to a cream cheese. Moulds for $\frac{1}{4}$ -lb. sizes should be made of tinned copper sheeting, $3\frac{1}{2}$ in. long, 2 in. wide and $1\frac{1}{8}$ in. deep. If kept cool and made from fresh buttermilk, the cheese should keep quite good for a week.

During the heating process the buttermilk should be gently stirred and, when ready for draining, it should be strained while quite hot. The finished cheese should be smooth and creamy.

(2) The second method is to mix two-thirds of buttermilk with one-third of new milk, bring to a temperature of 80° Fahr., add one dram of rennet to each 4 gal. of mixture, and stir in the rennet for a few seconds only. It should then be allowed to stand for one hour, when the curd should be dealt with as

described above. If the buttermilk has been used sour the curd will separate in a granular form. If fairly sweet it will form a firm coagulum, and if coagulation takes place the curd should be cut with a knife into $\frac{1}{2}$ -in. cubes at the end of an hour, and then ladled out into the cloth-covered draining rack. The cheese should be creamy in texture and free from grittiness.

(3) A pressed cheese may be made with separated milk mixed with not more than 20 per cent. of buttermilk. In this case the buttermilk should be used as fresh and as sweet as possible. The cheese should be made up as for Cheddar or for the Dorset skim-milk cheese. The addition of buttermilk in the manufacture of skim-milk cheese greatly improves the texture and flavour. In Leaflet No. 231, "Cheese-making for Small Holders," the manufacture of small pressed cheeses is described.

A very useful cheese can be made from mixed skim-milk and buttermilk in the proportions given above (as described under "Pressed Cheese No. 2," in the leaflet), only it requires a greater amount of milk to make a full-sized cheese. About 7 gal. of the mixture make on an average two cheeses of $2\frac{1}{2}$ to 3 lb. in weight.

(This note is also issued separately as Leaflet No. 324.)

THE table below has been compiled from felled trees measured by the Board's officers engaged on the collection of statistics as to the rate of growth of timber. The methods employed were similar to those used for constructing volume tables for the larch, which were published in the issue of this *Journal* for March, 1918.

**Preliminary
Volume Table for
Scots Pine.**

Measurements of 540 trees were used in constructing the tables, viz. :—

30—40 ft. high	41 trees.
40—50 "	166 "
50—60 "	133 "
60—70 "	120 "
70—80 "	63 "
80—90 "	17 "

Total 540 trees.

The volumes given in the table are tape under bark. The proportion of bark in Scots pine trees varies from 6 to 16 per cent. of the volume of the unbarked tree with an average of rather less than 10 per cent. The under-bark measurements of the table must therefore be increased by a corresponding amount if over-bark volumes are required.

Volume Table for Scots Pine.

APPARENTLY the Feeding Stuffs Section of the Ministry of Food have directed manufacturers of concentrated feeding stuffs to store their summer output so that it may go to increase the supplies for next winter. In these circumstances, there is little to be said about supplies on the markets.

**Notes on Feeding
Stuffs in July:**

*From the
Animal Nutrition
Institute, Cambridge
University.*

The policy is no doubt on the whole a wise one, but it must be admitted that occasions do arise on most farms when a small supply of concentrated food is really necessary, even when grass is abundant as it is at present. Every farmer should have in hand a small stock of bran for foaling mares and calving cows. It is believed that arrangements have been made to release a little cotton cake, which by the way does not keep well, for maintaining the milk supply in districts where the grass is liable to fail suddenly in case of even a short drought.

The present time also offers a favourable opportunity for reconsidering the system on which priority certificates are issued. The weakest point in the system is the shortness of the period which the certificates cover. The system was started last winter when the shortage of concentrated feeding stuffs was so acute that hand-to-mouth buying only a month ahead was the best that could be done. During the breathing space afforded by the present abundance of grass, however, it should be possible to amend the system. There seems to be no adequate reason why a farmer who presents a careful estimate of his next winter's needs, and is willing to sign a guarantee to store feeding stuffs until winter arrives, should not be granted a Priority Order, which would enable him to buy for his winter's needs. This would distribute transport more equally throughout the year and decrease the cost of the feeding stuffs to the farmer by the value of the rent, supervision and labour required for bulk storage.

Mr. Prothero has issued a warning to farmers as to the need of the greatest economy in the use of what remains of last year's hay crop.* Farmers must remember that they are not the only people who own livestock. From the national point of view, army and transport horses are as necessary as agricultural horses, and they, too, need hay. Any of last year's hay left over on 30th September will be reserved for town and army horses. The patriotic farmer will spare all he possibly can.

The same remarks apply also to wheat and oat straw.

* See p. 347 of this *Journal*.

This year's hay crop will be dealt with on the same lines as last year, except that the price of hay taken for the Army may be somewhat increased.

Since the appearance in these Notes of the last table of prices of feeding stuffs, a new Order* has appeared varying to a slight extent the maximum prices of cattle feeding stuffs. A new table, showing the present position with regard to feeding stuffs, is here given. The prices shown refer to quantities over two tons, and do not include transport charges and charges for bags. For quantities under two tons additional charges are allowed, varying from 5s. a ton for lots over 5 cwt., to 1s. 6d. a cwt. for smaller quantities.

† In continuation of the note on couch-grass rhizomes for feeding purposes which appeared on p. 1441 of the issue of this *Journal* for March last, experiments have recently been made in Leipzig-Lindenau on a large scale by Herr von Fehrentheil.†

The Utilisation of Couch-Grass.

These experiments indicate that couch-grass (*Agropyrum repens*, Beauv.) is of substantial value as a food substitute in the existing shortage of feeding stuffs. According to the experiments couch-grass forms a valuable foodstuff for cattle and poultry. After the removal of any soil adhering to it the couch-grass is threshed and dried, and as "couch-hay" has quickly become a valued feeding-stuff among farmers. It is claimed that in feeding value it ranks with good meadow hay. It contains 10.37 per cent. crude protein, 4.93 per cent. digestible protein, and 1.36 per cent. fat. During the Thirty Years War, meal ground from the stolons of couch-grass was used to make a very palatable bread. Meal made from young nourishing grass, clover, lucerne, or certain weeds added to rye-meal has lately been employed with great success in the preparation of a really nourishing and delicious bread which will keep for a considerable length of time. The utilisation of couch-grass in these ways is strongly recommended by Strecker during the present shortage of foodstuffs.

Attention may also be called to an article on "The Composition and Agricultural Value of Couch and Couch Ashes," by John Hughes, F.I.C., which appeared in the *Journal of the Bath and West and Southern Counties Society*, Vol. VIII.

* The Cattle Feeding Stuffs (Maximum Prices) Order, 1918 (Order No. 173, dated 7th February, 1918). See this *Journal*, March, 1918, p. 1474.

† From an article by Professor Dr. Strecker (Leipzig) in the *Illustrierte Landwirtschaftliche Zeitung*, October 20th, 1917.

(Fourth Series), 1898. The writer gives analyses of specimens of couch and samples of the soil which produced them, obtained from farms situated in three counties of England, and examines the results of his analyses. He shows the respective values of burnt couch and decayed couch heaped as a compost for manurial purposes, and also points out that this weed, when properly cleaned, and freed from adhering dirt, should prove a useful feeding material in times of scarcity.

Trials upon a small scale recently made in this country indicate that some difficulty may be experienced in getting cattle, sheep, or horses to consume the dried couch roots, but that pigs and poultry consume them freely.

As instances of the great value of co-operation in agriculture the following accounts of the work of some farmers' co-operative societies (taken from the *A. O. S. News and Notes*, May, 1918), may be of interest :—

Successful Co-operative Societies. *The Eastern Counties Farmers' Co-operative Association, Ltd.*—This society, which has just held its annual meeting, has had a record year, both as regards membership and turnover. With a membership of 1,883 (610 new members being enrolled during the year) the turnover has been £701,000. A realised surplus of £15,660 has enabled the society to refund a bonus to members in respect of their purchases through the Corn and Machinery Department of 4d. in the £, to reserve for bad and doubtful debts £3,100, to place to special reserve £5,300, and to carry forward £10,935.

To cope with the expansion of business, the committee has secured additional premises in Princes Street, Ipswich, and has also taken over the store formerly occupied by the Tendring Hundred Farmers' Society at Weeley.

Allendale Farmers', Ltd.—This society had a turnover of £36,800 in its last year (exclusive of auction sales amounting to £13,300), being an increase of £9,000. Notwithstanding that the supply of feeding stuffs of all kinds has been limited, the amount of trade done in this department has exceeded that of any previous year. With a view to utilising to the best advantage the surplus milk in the summer months, a cheese plant was installed and a large quantity of "Allendale" Cheddar cheese manufactured. The year's trading resulted in a realised surplus of £1,242.

The Guildford and Mid-Surrey Farmers' Co-operative Association.—The tenth annual report of the Guildford and Mid-Surrey Farmers' Co-operative Association shows that the membership has steadily risen from 115, representing an acreage of 17,790, in 1908, to 338 in 1917, representing 52,510 acres. During the same period the nominal capital has increased from £331 to £1,312; the turnover from £9,535 to £33,090, and the realised surplus from £1 3s. 7d. to £905 16s. 6d.

During the past year the association has purchased new premises in Guildford. The purchase money was raised by subscriptions from members, and the amount required was over-subscribed. The members' interests are secured by a mortgage on the property. Further enterprise was shown by the association engaging the services of a competent

engineer, and a great deal of repair work to agricultural machinery has been carried out. This new development has been a striking success. Everything points to the continued prosperity of the association.

Littleton and Badsey Growers, Ltd.—To quote from the report of the Littleton and Badsey Growers, Ltd., "the past year has been an eventful one in the history of the society." Great progress has been made. The membership has risen to 144, and the turnover—£16,390—is considerably more than double the previous year's. This has resulted in a realised surplus of £1,439, of which £1,342 has been placed to reserve.

Brandsby Agricultural Trading Association, Ltd.—The half-yearly report and statement of accounts of the Brandsby Agricultural Trading Association, Ltd., show very satisfactory results. On a turnover of £33,870 a realised surplus of £741 has resulted, enabling the committee to declare a dividend of

1s.	in the £	on members' store purchases.
6d.	"	" dairy sales.
4d.	"	" agricultural purchases.
2d.	"	" sales.

The membership has increased from 327 to 352 during the half-year. The report strikes the right note in saying that "to obtain the greatest advantage of present developments farmers must combine in order to protect their own interests, and to receive a legitimate return for their industry, whilst ensuring to the people of this country food at fair and reasonable prices."

Melksham and District Poultry Society, Ltd.—Melksham and District Poultry Society, Ltd., has had a good year, dealing in nearly three-quarters of a million eggs, with a cash turnover of nearly £7,000, and a realised surplus of £207. The society has sub-depots at Atworth and Holt, and contemplates extending its operations to several of the neighbouring villages. The membership has steadily increased by 22 during the year.

The Recruiting Movement.—The recruiting campaign in connection with the Women's Land Army is being pushed vigorously in the provinces as well as in London. Recent recruiting tours in East and West Sussex and

Women's Work on the Land. in the North Country have proved very successful. Over 1,000 recruits were enrolled

at Liverpool in three days; simultaneously Sheffield supplied 130, Leeds 97, Stafford 60, and Barnsley 50. In East Sussex 100 women signed on at Worthing, 70 at Bognor, and 66 at Horsham. Plymouth, during the week ended 24th May, 1918, reported 60 recruits. Appeals are being delivered in many provincial theatres and cinema halls nightly on the work of the Land Army and the names of recruits taken. The demand for skilled labour, for individual women as well as for gangs, is far beyond the available supply. Strong women desirous of joining the Land Army should apply to the new recruiting office, 135, Victoria Street, Westminster, S.W. 1, where full information as to terms of service, &c., will be supplied.

A Farmer's Tribute.—At many recent recruiting meetings of the Women's Land Army valuable testimony to the usefulness of woman labour on the farm has been offered by agriculturists who have employed such labour. A case in point occurred at one of the Oxford Street

meetings in London recently. A farmer in the crowd was saying such appreciative things about the Land Army that he was invited to address the meeting. He willingly did so, and, among other things, said he had a barrister's daughter, a doctor's daughter, and a professional singer, besides a number of other women of various classes, working with him. It did not matter to what class they belonged, he said, they had all done well. So well, in fact, had they done, he declared jocularly, that he had made £5 more profit on each pig this year than ever before. Calves, delicate from birth, had also been saved by the capable and careful handling of the women. On his farm four women and a boy had ploughed 57 acres of land most satisfactorily. In most districts, of course, the pre-war prejudice against the employment of women has disappeared under the stress of circumstances and as a result of actual experience in the employment of women.

The Women's Institutes.—Thirteen new institutes were reported during the third week in May. The Saltford (Somerset) Women's Institute has started the communal keeping of pigs. A Live-stock Committee has been chosen from the members of the Institute. Three depots have been arranged where waste from households, gardens, etc., is sent. The styes are rented from a man who undertakes to feed and look after the pigs. Any member of the Institute can be a member of the pig club by purchasing a 1s. share, and shares up to 5s. may be held by any member. Honorary members must take at least five shares. Boys who collect the waste are allowed to become shareholders by paying 3d. When pigs are killed, members may purchase the meat in proportion to their shares. A certain proportion of profits from sale will be put aside as a reserve fund, the remainder of the profit will be returned as bonuses to members, honorary or otherwise. This pig scheme has been drawn up on the advice of the Agricultural Organisation Society representative in Somerset.

Training for Land Women.—During the week ended 18th May, 1918, 20 new practice farms were sanctioned in connection with the Women's Land Army, making provision for the training of between 70 and 80 recruits. At the training centre at Drayton St. Leonards the women are given special facilities for acquiring a good all-round knowledge of horse work. There are 20 horses on the farm and they are looked after entirely by women. One woman, who went through the first course at the centre two months ago, is now acting as carter for the farmer who attends the centre, and is doing excellently. Among her other charges are 4 mules.

During the week ended 31st May, 1918, 28 new training centres were opened to accommodate 95 land women. Many new gang hostels have been sanctioned.

South Court House at Leighton Buzzard (Bucks) has been opened as a training centre for 50 women.

Some Work Done by Women.—Six new women tractor drivers have recently begun work in the Isle of Ely and the tractor representative reports most favourably upon them. A new tractor training centre for women has been started at Oxted. The work of the women on the Fordson tractors in the Holland area of Lincolnshire is "spoken highly of." The Chairman of the Labour Committee reported that the women had given great satisfaction, and other members of the Committee stated that their land had been ploughed "splendidly" by the women and the Fordson.

The Women's War Agricultural Committee for the Louth District have devised a good scheme for helping to preserve the fruit supplies. They had £15 in hand as their share of the surplus in the county from the sugar distribution. It was decided to spend this on two canners, one to be stationed at Louth, and the other to tour the villages. A trained operator will demonstrate the use of the canner. Every village should possess a canner for conserving food and a sprayer to prevent potato disease.

It is proposed to teach land women in the eastern counties how to "plash" hedges, so as to keep them continually employed during the winter. Others are to be taught threshing, or their services will be utilised in the turnip fields. It is suggested that "migratory groups of women may advantageously be organised."

The Brecon Committee have engaged four women, who have been working on the tractors, to cut thistles in the corn fields; and a number of unskilled women are to be employed under them.

In an efficiency test of 21 members of the Land Army held at Shrewsbury there were 13 entries for milking, 3 for ploughing, 5 for harrowing, and 9 for grooming and gearing. The highest point of efficiency was reached by one woman in ploughing and another in grooming. Several came as high as 99 per cent., 98 per cent., and 95 per cent., and none of the entries was lower than 75 per cent.

Allotment Progress.—The Food Production Department report that at Tarporley (Cheshire) every one of the 600 householders is cultivating either an allotment or garden this year for

Notes on Allotments. food production purposes. At Abergele and Pensarn 66 per cent. of the householders have food production plots. At Daventry (Northants) 572 out of 800 householders are cultivating allotments, all of which have been acquired by private agreement between the allotment holders and the landowners.

Among the larger towns that have done extremely well in the matter of allotments is Southampton, which has already provided 3,000 plots (242 acres) comprising practically all the available land conveniently situated. An effort, however, will be made to provide a further 300 allotments next season.

Three acres of land have been recommended for next-season allotments at Tythegstone Higher (Glam.). This land will probably be taken over immediately the hay crop has been harvested.

In many parts of the country landowners have shown an admirable spirit in relation to the provision of land for allotments by private treaty. An instance is reported by the Food Production Department from Haverhill (Suffolk) where 65½ acres of land have been provided by voluntary arrangement. This land has been cut up into 1,023 allotments; as there are only 1,056 houses in the town Haverhill must come very near to establishing a record in allotment holding. Some of the men to whom land has been allotted are on active service, and, in their absence, the allotments are being successfully carried on by their womenfolk.

Allotment Tenure.—In reply to inquiries, it is stated by the Food Production Department that war-time allotment holders who may receive notice to quit and be unable to arrange matters satisfactorily with the owner of the land they occupy should communicate with the Department. Advice has been given in a number of cases and practical

assistance of various kinds in others. During the last week in May 11 allotment holders occupying an acre of land at West Molesey, and 17 allotment holders occupying $2\frac{1}{2}$ acres at Deddington (Oxford), having received notices, appealed to the Department. An inspector was able in both cases to arrange for a continuance of the tenancy.

Fertilisers for Allotment Holders.—Allotment holders and small growers generally are informed that the Food Production Department is making arrangements with all "Approved" agents for the sale of fertilisers in the 1918-19 season to supply sulphate of ammonia, superphosphate, and basic slag in 14 lb., 28 lb., 56 lb., and 1 cwt. lots to meet the needs of allotment holders and small growers. It is hoped that this arrangement will obviate a difficulty experienced in some districts in the past season.

OFFICIAL NOTICES AND CIRCULARS.

N.B.—The Orders which may be mentioned in this section of the JOURNAL may usually be obtained at the price of 1d. each from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, and 28, Abingdon Street, London, S.W. 1; 37, Peter Street, Manchester; and 1, St. Andrew's Crescent, Cardiff.

THE following Interim Report of the Director-General of Food Production (for England and Wales) was issued for publication on 29th May:—

Results of Food Production Campaign, 1917-18. It is now possible to give some results, to date, of the Government's efforts to increase home-grown supplies of corn and potatoes.

Increase in Acreage of Corn and Potatoes. An official and compulsory census, obtained on 27th April, 1918, from occupiers of land in England and Wales, shows the total acreages up to that date. (See table on p. 338.)

Increase in Tillage Area.—Complete returns of the acreage of grass land ploughed are not yet available, but a compulsory census, taken on 11th March, 1918, showed that over 1,800,000 acres of "Permanent" grass in England and Wales had been broken up by that date, and it is estimated that a total addition of not less than 2,500,000 acres to the tillage area of England and Wales (as compared with 1916) has now been made.

If, as may be anticipated from the recent forecasts of the Boards of Agriculture for Scotland (300,000) and Ireland (1,500,000), the corresponding addition to the tillage area in those two countries will approximate to 1,800,000 acres, the total for the United Kingdom will be well over 4,000,000 acres.

Home-grown Breadstuffs.—The foregoing figures indicate that the total acreage in the United Kingdom under wheat, barley, and oats, in 1918, will be the highest ever recorded in the history of British agriculture. The acreage under potatoes will be the greatest since 1872. Particulars of other crops are not yet available.

It is, of course, not possible to foretell the quality of the coming harvest, but, speaking generally, the present condition of crops is very promising and gives reasonable hope of at least an average yield.

Proceeding upon this assumption, and further assuming that (after deducting seed and light corn) the whole of the wheat and barley crops,

one-fifth of the total oat crop, and one-quarter of the potato crop (i.e., the surplus above normal consumption) could be made available for bread-flour in case of need, it may be reckoned that the *United Kingdom* harvest of 1918 could provide 40 weeks' supply of bread-stuffs for the entire population, at the present scale of consumption and on the existing basis of milling.

Feeding Stuffs.—The *English and Welsh* harvests would further provide concentrated feeding-stuffs for animals (in excess of the normal

Food Production Department
May 1918

FOOD PRODUCTION IN ENGLAND AND WALES **INCREASES IN CORN, POTATOES & ALLOTMENTS (1917 & 1918)**

home production of oats reserved for this purpose) to the amount of some 500,000 tons, besides additional oat straw equivalent to at least 350,000 tons of hay.

Saving of Tonnage.—Reckoned in tonnage, the *net* saving in shipping resulting from the increased production of corn and potatoes, in England and Wales alone, should amount in the coming year to 1,500,000 tons.

HOME-GROWN BREADSTUFFS.

Shaded portions show number of Weeks during which the United Kingdom has been or will be Self-supporting in the years 1916-17, 1917-18, and 1918-19.

This Diagram is calculated upon the different standards of milling which were actually in force in each of the years named

FOOD PRODUCTION DEPARTMENT.

May 1918

Allotments.—The foregoing figures relate only to holdings of one acre and upwards and take no account of the increased produce from allotments and gardens. These, however, contribute very largely to the supply of home-grown food. The increase in the number of allotments alone, since 1916, is not less than 800,000 in England and Wales, or 140 per cent.

The additional weight of foodstuffs produced by this expansion may be reckoned at not less than 800,000 tons above the normal.

CORN AND POTATOES.
(*England and Wales only.*)

Crop.	Acres.	Increase Over 1916.		Remarks.
		Acres.	Per-centage.	
Wheat	2,665,000	752,000	+ 39	Highest recorded since 1882.
Barley	1,490,000	58,000	+ 11	—
Oats	2,820,000	735,000	+ 35	Highest on record by 20 per cent.
Rye, Dredge Corn, and Pulse ..	682,000	280,000	+ 69	—
Potatoes	645,000*	217,000	+ 50	Highest on record by 27 per cent.
Total acreage of Corn and Potatoes (England and Wales) ..	8,302,000	+2,042,000		

* Ministry of Food Census.

Conclusion.—These results (so far as Great Britain is concerned) have been achieved under exceptional difficulties created by shortage of labour. In England and Wales alone there are over 200,000 fewer male labourers on the land to-day than in the year before the War, after crediting all military and prisoner labour furnished by the Government. This fact, by itself, is a sufficient proof of the energy, resource, and patriotism with which all sections of the agricultural community have devoted themselves to the service of their country.

N.B.—The diagrams on pp. 336-7 will help to illustrate the main points in the Memorandum.

THE following Letter (No. C.L. 26/H.), dated 21st May, 1918, has been addressed to Horticultural Sub-Committees by the Food Production Department of the Board :—

Rabbit Breeding

Scheme:

Circular Letter.

SIR,—I am directed to refer to the Circular Letter issued by this Department on the 2nd May, and to say that the Department, in order to encourage the more general keeping of rabbits, has elaborated a scheme which it is hoped will be adopted throughout the country.

As is generally known, the chief obstacle to the wide extension of rabbit keeping at the present time lies in the fact that suitable utility breeding stock is scarce, difficult to obtain, and costly. An essential feature of the scheme which is being put forward by the Department consists in the adoption of measures to secure and to increase the breeding stocks of suitable strains, and to put those stocks to the best use for the purposes of raising rabbits which may be purchased by all those who wish to keep rabbits for table purposes.

It is believed that this end will be secured by the establishment of breeding centres, and the National Utility Rabbit Association, which has been formed at the instance of the Department, is now engaged in establishing a central breeding station in London, and is also prepared to lend its assistance towards setting up similar breeding stations (called "100-Doe Centres") in different parts of the country.

Each breeding station established in this way will be required to give an undertaking to maintain a prescribed number of breeding does in the station, and to supply a prescribed percentage of young rabbits to clubs affiliated to the Association, and also to provide individuals at a price agreed upon between the breeding station and the National Utility Rabbit Association. Needless to say, the Department will use every means to secure that the prices thus agreed upon are such as to make rabbit keeping possible for any section of the community. The breeding station will also be required to supply, so far as the existing stocks will allow, breeding does to authorised small breeding centres (called "20-Doe Centres"), to be established under the auspices of the Association and in relation with the larger 100-Doe Centres.

It should be clearly understood that the present shortage of breeding does cannot be remedied in the immediate future, and that it will therefore be impossible for the breeding centres to supply, on any considerable scale, does in young to private individuals. The whole object of the scheme is to make good the present shortage of supply of suitable breeding stock by assembling in centres, and keeping strictly and only for breeding purposes, does of suitable strains and at present available.

Whereas, therefore, it will not be possible before some months have elapsed to meet demands which are likely to arise for supplies of does in young, it will be possible, at all events, in a large measure to meet the demand which exists, and will increase, for young rabbits for keeping for both table and breeding purposes.

It is proposed that, in order that the details of the scheme may be outlined to the Committee, an officer of the Department should attend your Committee at an early date, and I shall be greatly obliged if you will indicate to me what are the earliest alternative days on which it would be possible for you to summon your Committee, in order that the Department's proposals may be placed before them.

I should add that both this Department and the National Utility Rabbit Association are anxious that the scheme for largely increasing the numbers of rabbits kept in the country shall have the advantage of the active assistance of the Horticultural Sub-Committee.

I am, etc.,
(Signed) G. F. MIDDLETON,
For Controller of Horticulture.

A NATIONAL rabbit-breeding scheme has been started by the National Utility Rabbit Association and the Food Production Department. The

**The National
Rabbit Scheme.**

Association comprises the leading rabbit breeders and rabbit keepers of the country. It is establishing a central breeding station and stud exchange at Mile Street, Vauxhall, S.E., where 1,000 does will be kept. The primary object of the Association is to build up as quickly as possible a large supply of the best pedigree stock, which will be sent out to district breeding centres to be set up throughout the country. These, in their turn, will supply breeding stock to smaller stations, formed in association with the district centres. Each of the larger district centres will have 100 breeding does; the smaller stations will have 20. It is hoped that all allotment societies, food production societies, and women's institutes, and many factories, munition works, schools, camps, and so on, will form rabbit clubs in affiliation with the Association. The clubs will, in the majority of cases no doubt, manage the breeding centres. Most of the existing rabbit clubs have signified their willingness to affiliate to the new Association.

The Association will work in close co-operation with the Horticultural Sub-Committees of the Agricultural Executive Committees of the counties, and it is expected that the Horticultural District and Village Committees will play an active part in the development of the rabbit scheme.

The first club started in London under the auspices of the new National Association is at the Royal Mews, Buckingham Palace. About £100 has been subscribed; there are 90 members or employees of the Royal Household in the club; 12 breeding does have been installed—these represent all the best utility types of rabbit and have been collected from the chief breeders of the country—and shortly 50 does and 10 bucks will be installed. It is hoped that the example of the Royal Family in assisting in the establishment of this club will be followed by the proprietors of all the leading mews in London.

Full particulars as to the Association, as to the best breeds to keep, as to war-time rations for rabbits, etc., can be obtained on application to the Food Production Department, 72, Victoria Street, S.W. 1.

THE following Memorandum (No. C.L. 161/M. 1), dated 18th May, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the

Supply of Harvest Board :—

Carts and Lorries. It will not be possible to supply in time for the hay harvest more than a small number of the carts and lorries referred to in Circular No. 139/M. 1.*

The Department do not consider it practicable to arrange for the manufacture of raves and ladders to be distributed from central points for fitting to carts and lorries already in the counties.

Committees requiring carts and lorries for the hay harvest should, therefore, arrange locally for raves and ladders to be fitted to the carts and lorries which have already been supplied. The maximum cost to the Department of raves and ladders is for carts £4 10s., and for lorries

* See this *Journal*, May, 1918, p. 206.

£6 10s. a set, and this amount must not be exceeded by Committees without reference to this Department. Every effort should be made to obtain raves and ladders at less than these figures.

If a permit for timber is required forms should be obtained from the Timber Controller, Caxton House, Westminster, S.W. 1, and should be properly filled in, as directed, and then sent to the Department for the addition of a recommendation to Form "C." The forms will then be forwarded by the Department to the Timber Controller.

If a priority certificate for wrought iron or mild steel is wanted, full particulars giving sections and quantities and supplying firms should be sent to the Department, who will then apply to the Ministry of Munitions.

THE following Memorandum (No. C. L. 184/M. 2), dated 5th June, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Labour Employed on
Steam Tackle.**

With reference to C. L. 79/L. 1, the attention of Agricultural Executive Committees is drawn to the importance of the retention of labour engaged in connection with steam tackle. Besides the work which is normally undertaken, a large amount of land was broken up by means of steam tackle last season, and steam tackle will be of the greatest importance during the coming ploughing season. The labour employed is highly skilled and at present irreplaceable, and any further reduction in the number of men engaged would entail the laying up of sets of tackle, a position which the Department is most anxious to avoid.

When the question of the inclusion of such men in List A (1) or List A (2) comes before a Committee, it is desirable that, if the set of tackle upon which a man is employed is energetically and efficiently worked and the man himself is an efficient workman, very careful consideration should be given to the case before the man is released for military service.

THE following Memorandum (No. C. L. 80/L. 1), dated 3rd June, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Soldier Labour.

In view of the large number of soldiers now engaged on agricultural work, it is increasingly important that as much supervision as possible should be exercised over the work which they are called upon to perform. Except with special authority these men should be engaged on farm or market-garden work, and it is the duty of the County Agricultural Executive Committees to allot them to the farms on which their services are most urgently required and when other sources of labour (women, prisoners, etc.) are not available.

Steps must also be taken, in the manner best suited to each locality, for periodical inquiries to be made either by a personal visit by an officer or member of the district committee or by reference to the police as to whether the soldiers are employed at the place and at the work to which they were sent out. In this matter committees should seek the co-operation of the Commandant of the distribution centre, and in any cases where inquiry shows that the soldier should be withdrawn the Commandant should be asked to take the necessary action at once.

Commandants of agricultural distribution centres sometimes experience difficulty in getting about the country to visit farms and generally attend to the numerous questions arising in connection with soldier labour employed in agriculture. The Department suggest that whenever it is possible assistance might be given to Commandants in this matter by combining visits with those made by officers of your committees.

THE following Memorandum (No. C. L. 81/L. 1), dated 3rd June, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Civilian Prisoners
of War.**

The Department are informed by the Home Office that there are still available a number of able-bodied interned aliens accustomed to manual work who can be released for employment on the land under the conditions laid down in the Department's leaflet (F.P. 121 L. 1), a copy of which is enclosed.* Many of these men claim to have had experience of agricultural work, whilst some are mechanics who claim knowledge of motor implements, steam-plough tackle, traction engines, etc. Others are fitters and a few are blacksmiths.

The attention of farmers in the county should again be drawn to the possibility of obtaining useful labour from this source.

ACCORDING to the foregoing Memorandum (No. C. L. 81/L. 1), it is expected that a small number of Danish agricultural workmen will shortly be available for employment in this country. These men are being recruited by the Ministry of Labour, and every care is

taken to obtain men who are definitely qualified to undertake agricultural work. While it is not advisable, in view of the small number of these men who are likely to come to this country, to advertise this labour widely, Committees will, no doubt, take steps to get some of the men placed in the county on work connected with food production. Applications from farmers should be forwarded to the Ministry of Labour, Employment Department, Queen Anne's Chambers, Westminster, S.W. 1, and should be made on a form, a copy of which is enclosed.*

THE following Memorandum (No. C.L. 76/L. 1), dated 17th May, 1918, has been addressed to District Commissioners and Secretaries of

**Exemption of Men
Employed in
Connection with
Agricultural Tractors,
Steam Ploughs and
Threshing Machines.**

Agricultural Executive Committees by the Food Production Department of the Board :—
Telegrams were issued by the Ministry of National Service on the 27th ultimo and 2nd instant, to the effect that it was not intended that the makers, erectors, or repairers of agricultural implements, tractors, steam ploughs, or threshing machines, and attendants, drivers, or mechanics employed thereon, should be decertified by the Withdrawal Order of 9th April, Form R. 49. Agricultural Executive Committees were notified accordingly by this Department.

The Ministry have now issued instructions by telegram 1976/R.1 of 13th May, that recruiting authorities may use their discretion as to the

* Not here printed.

posting of the classes of men of these occupations, whether within the ages covered by Royal Proclamation of 20th April or not, bearing in mind the need for men for the Army and the importance of food production. Recruiting authorities can, therefore, now suspend the calling up of men of the ages and grades or medical categories affected, with a view to allowing time for substitution in urgent cases if referred by Executive Committees to local recruiting authorities direct for submission to them if required to Regions. Committees should clearly understand that only very urgent cases may be submitted, and also that the discretion to be exercised by recruiting authorities applies to the men concerned who were regarded as being affected by the Withdrawal Order of the 9th of April and those who are concerned by the Proclamation of the 20th April.

This consideration is important, as some Committees have thought that the telegrams of the 27th of April and the 2nd of May refer to cases covered by the Proclamation, whereas they apply only to cases covered by the Withdrawal Order of 9th April. These Committees have accordingly omitted to submit under paragraph 5 of this Department's Circular Letter of the 26th ultimo (66/L. 1)* cases which might have been allowed to go to the Appeal Tribunal. Provision is now made by the new instructions referred to herein, by which any omission in these occupations only may be met.

THE following Notice was issued by the Food Production Department of the Board towards the end of May :—

Binder Twine. The Food Production Department of the Board has made arrangements for the supply of additional quantities of binder twine to meet the needs of the coming harvest. The present price to farmers is 120s. per cwt., delivered to farmer's nearest railway station, or taken from dealer's or merchant's local store. Any dealers or merchants who are unable to obtain sufficient twine to meet current orders from the makers from whom they usually buy should make application to the Food Production Department, 72, Victoria Street, London, S.W. 1, without delay.

THE following Memorandum (No. C.L. 49/C. 1), dated 18th May, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Damages to Crops and Fences. In consequence of representations that have been received from various parts of the country to the effect that, owing to the large extension of the arable cultivation, the existing legal provisions are not sufficiently effective to prevent damage to growing crops, the Board of Agriculture have (with the concurrence of the Home Office) obtained an amendment to the Defence of the Realm Regulations by which it has been made a summary offence against those Regulations to do such damage.

Any person who, without lawful authority or excuse, damages any growing crops or any hedge or fence on any agricultural land is liable to a fine of £100, or six months' imprisonment with or without hard labour, or both. The offence is triable by a Court of Summary Juris-

* See this *Journal*, May, 1918, p. 241.

diction. A prosecution can only be instituted by an officer of police, or by a person authorised by the Government Department concerned.

It is not necessary that there should be any notice displayed on the land in order to prove the offence, where damage of this kind has been committed.

If the damage is done by a crowd (as frequently happens when aeroplanes alight on cultivated land) any member of the crowd is deemed to have caused the damage unless he proves the contrary.

Trespass without doing actual damage to crops or fences is punishable only in respect of allotments or field gardens, and only where a notice giving the effect of Regulation 2N is conspicuously displayed on the land.

The full text of Regulation 2N, as now amended, is as follows :—

2N. If any person without lawful authority or excuse damages any growing crops or any hedge or fence on any agricultural land, or if any person without lawful authority or excuse enters or remains on any land

(a) of which a Government Department or any body or person authorised by a Government Department is in possession under the powers conferred by Regulation 2L ; or

(b) which has been provided for use as allotments or field gardens under that Regulation or otherwise, and on which there are growing crops,

and on which there is conspicuously displayed notice of this provision, he shall be guilty of a summary offence against these Regulations.

Where any such damage as aforesaid is caused by the assembly of a number of persons any one of such persons shall be deemed to have caused such damage unless he proves the contrary.

THE following Notice was issued by the Food Production Department in May :—

Destruction of Farm Pests.

Some interesting particulars about the destruction of rats, rooks, house sparrows, and other farm pests have been sent in to the Food Production Department recently. They show that where the matter is taken in hand systematically any reasonable expenditure in this direction is an excellent investment. For example, in Hertfordshire 53,632 rats, 33,990 sparrows, and 14,581 sparrows' eggs are said to have been destroyed in a twelvemonth at a cost of only £261 11s. Assuming the accuracy of the estimate that rats alone cause about £40,000,000 worth of damage to food-stuffs in this country annually, and accepting the very modest sum of 1s. per week as the cost of feeding a farm rat, it will be seen that the total bonus money paid in Hertfordshire must have been saved many times over on the rat account alone, and the measures taken must be regarded as extremely economical.

THE following Memorandum (No. 48/C. 2), dated 17th May, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Cartridges for the Destruction of Farm Pests.

Some doubt appears to exist as to the procedure relative to the supply of cartridges for county pigeon shoots and the destruction of vermin.

A Committee should order from a cartridge retailer, in the form S.C. 3, issued by the Ministry of Food, a stated number of cartridges,

which, however, will not be delivered to the Committee but will be retained by the retailer who will supply them to persons producing the Committee's authority to purchase. A Committee should not place orders for more than 1,000 cartridges in the hands of the same retailer until he has sent details of the sales, against the Committee's permits, of the supply placed with him for the Committee's account. When this supply is exhausted the Committee should inform the Ministry of Food how many shooters have been supplied with cartridges, and give to the retailer a further order in the form S.C. 3.

All retailers are receiving stocks monthly proportionate to their sales in 1916, and it is important that the Committee should grant an authority to purchase only where they consider that the applicant is unable to obtain cartridges in the ordinary way from his dealer.

THE following Letter (C.L. 24/H.), dated 16th May, 1918, has been addressed to Horticultural Sub-Committees by the Food Production Department of the Board :—

**Reimbursement of
Marketing Societies.**

SIR,—I am directed to transmit herewith, for the information of your Committee, a copy of a Memorandum showing the conditions under which the Department are prepared to reimburse the County Marketing Society formed by or under the control of a Marketing Executive or the Horticultural Sub-Committee to the extent of a sum not exceeding £250 in the event of the accounts of the first year's working showing a loss to that extent. I am to point out that the Department have agreed to pay a salary of £100 a year to the secretary of a Horticultural Sub-Committee, provided that he also acts as secretary of the Marketing Executive.

In several counties the services of an officer of the education staff of the County Council have been lent to the Horticultural Sub-Committee, and in some cases this officer is acting as secretary. In such cases the Department are of opinion that some special arrangements should be made for the Marketing Executive, and it ought to be possible to find in nearly every county an honorary secretary who would be prepared to do the work, provided adequate clerical assistance could be given.

The Department wish to make it quite clear that as the work of the Marketing Executive involves the raising of capital and the formation of a co-operative society, any expenses incurred by the society must be met from the society's own funds and not from grants or funds of the Agricultural Executive Committee.

I am to suggest that in any county where a co-operative society is formed for marketing the Horticultural Sub-Committee should name its society the "(name of county) Fruit and Vegetable Society, Ltd.," and so ensure uniformity throughout the country.

I am, etc.,

(Signed) G. F. MIDDLETON,
For Controller of Horticulture.

ENCLOSURE.

Memorandum of the conditions under which the Food Production Department are prepared to reimburse any marketing society formed by, or under the control of, the Marketing Executive or the Horticultural Sub-Committee of an Agricultural Executive Committee, to the extent of a sum not exceeding

£250 in the event of the accounts of the first year's working showing a loss to that extent.

1. The Horticultural Sub-Committee must form a Marketing Executive on the lines indicated in the Department's Leaflet (F. P. 209/H).*

2. The Marketing Executive must form a co-operative society with a corporate existence.

3. The co-operative society so formed must raise sufficient capital to ensure the proper working of the society, according to the needs of the county.

4. The co-operative society must develop at least one central and three district or village depots.

5. The co-operative society, before starting business, must submit its rules in draft, and its proposed scheme of working to the Food Production Department for approval.

6. The co-operative society must appoint a market manager, but before actually making the appointment it must submit his application and all relevant papers, together with the salary proposed, to the Food Production Department for approval. The market manager must have a practical knowledge of the fruit and market garden produce trade, both wholesale and retail.

7. The co-operative society must submit to the Food Production Department a detailed statement of the number of paid officials, with their salaries, whom the society propose to employ at their headquarters, and also at the various depots. The Department would notify the society of any such appointments as they considered to be unnecessary, and if these appointments were still made by the society they would not be taken into account in determining if a loss had been incurred by the society.

8. The society must report any proposed expenditure on transport to the Department.

9. The society, through the Marketing Executive or the Horticultural Sub-Committee, must render to the Department a quarterly statement of the receipts and expenditure of the society. The statement should be signed by the secretary of the society, and countersigned by the chairman of the Horticultural Sub-Committee.

10. At the close of the first year of working a trading account for the year should be prepared and submitted to the Department, together with a claim of any loss shown by the account to have been incurred in the year's working. This account should be signed and countersigned, as instructed in the preceding paragraph, and should be audited by the auditor of the Agricultural Executive Committee.

AN Order (No. 516), dated 6th May, 1918, amending the Grain (Prices) Order, 1917, has been made by the Food Controller to the effect that :—

**Order Amending
the Grain (Prices)
Order, 1917.**

1. Clause 9 of the Principal Order† is hereby revoked as from the 15th May, 1918, and such Order as amended by an Order of the Food Controller dated the 5th April, 1918,‡ shall accordingly apply to grain suitable for seed.

AN Order (No. 519), dated 10th May, 1918, has been made by the Food Controller amending the Damaged Grain, Seeds and Pulse (Prices) Order, 1917,§ to the effect that :—

**Order Amending the
Damaged Grain,
Seeds and Pulse
(Prices) Order, 1917.**

1. The following words shall be inserted at the end of Clause 1 of the Principal Order :
" Provided that in the application of this Order to maize, it shall apply only to maize which has been damaged by water."

* Not here printed : to be obtained post free from the Food Production Department, 72, Victoria Street, London, S.W. 1.

† Order No. 820 of 1917. See this *Journal*, September, 1917, p. 673.

‡ " " 401 " 1918. " " May, 1918, p. 237.

§ " " 1174 " 1917. " " December, 1917, p. 1026.

2. Clause 2 (b) of the Principal Order shall be revoked as at the 20th May, 1918, and the following Clause shall be substituted therefor :—

“(b) On the occasion of the sale of any such article (unless it has been damaged by water) which has been re-conditioned or rendered more merchantable by kiln-drying or other like treatment, the maximum price shall be the price applicable according to the foregoing table together with the addition of a sum per quarter not exceeding the customary reasonable charge for such mechanical treatment. On the occasion of sale of any such article which has been damaged by water and which has been re-conditioned or rendered more merchantable by kiln-drying or other like treatment, the maximum price shall be in the case of Food Wheat 65s. per qr. of 480 lb., and in every other case the price applicable according to the foregoing table. When any article mentioned in the foregoing table has been mechanically treated by clipping, splitting, kibbling, bruising or grinding, or any other like method, the maximum price shall be the price applicable according to the foregoing table and provisions, together with the addition of a sum per qr. not exceeding the customary reasonable charge for such mechanical treatment.”

THE following Notice was issued by the Board on 24th May :—
The President of the Board of Agriculture and Fisheries desires to impress on farmers the necessity for the

The 1917 Hay Crop. exercise of strict economy in the use of that portion of the 1917 hay crop which remains.

It is essential that supplies required by horses engaged on transport work of urgent national importance should be maintained, and while “farmers and stock breeders are authorised to use a reasonable quantity of hay or oat or wheat straw in their possession for consumption by stock in their possession or control” yet the President agrees with the proposal of the Forage Department of the War Office that farmers cannot be allowed, as a rule, to retain in their possession any portion of the 1917 crop beyond the 30th September next. In exceptional cases where a farmer can prove that it is in the national interest that he should be allowed to retain any portion of the 1917 crop beyond that date, it is open to him to refer his case to the County Farm Produce Committee concerned, whose decision will be final and binding on all parties.

The Food Controller, in consultation with the three Departments of Agriculture, has fixed the following base prices* under the Potatoes Order (No. 2), 1917† for sound ware potatoes delivered by the grower on or after 15th May, 1918 :—

Base Prices for Potatoes.		£	s.	d.
(a) England and Wales	7	0	0 per ton.
(b) Scotland.				
(i.) Dumbartonshire, Stirlingshire, Linlithgowshire, Edinburgh, Haddington, and all counties south thereof (excluding the county of Bute)	6	10	0 „
(ii.) Argyllshire, Perthshire, Forfarshire, Kincardineshire, Fife, Clackmannan and Kinross	6	0	0 „
(iii.) The rest of Scotland including the county of Bute	5	10	0 „
(c) Ireland	5	0	0 „

* See Order No. 534, dated 15th May, 1918.

† Printed in this Journal, December, 1917, p. 1001.

Note.—The base price for England and Wales is the same as the guaranteed minimum price after 14th May, and no subsidy may be claimed by English or Welsh growers in respect of potatoes delivered after that date.

Contracts subsisting on 15th May for the sale of potatoes will be cancelled on that date in so far as potatoes not delivered before that date are concerned.

The restriction on the sale of "King Edward" ware potatoes grown on warp, silt, limestone and marshland in certain counties is now removed. (*National Food Journal*, 22nd May, 1918.)

Charges for Early Potatoes.

THE following maximum retail prices have been prescribed for early potatoes of the 1918 crop sold in Great Britain :—*

From 20th to 31st May	4d. per lb.
" 1st to 15th June	3½d. "
" 16th to 30th June	3d. "
" 1st to 15th July	2½d. "
" 16th to 31st July	2d. "

These prices apply both to imported and to home-grown potatoes. Subject to the operation of these prices the wholesale price of early potatoes up to the end of July will be unrestricted. (*National Food Journal*, 22nd May, 1918.)

AN Order (No. 518), dated the 8th May, 1918, has been made by the Food Controller to the effect that :—

1. In Clause 2 of the Principal Order,† the words "prescribed sum" shall be substituted for the words "sum of £6," and the following clause shall be added at the end of such clause :—

"The prescribed sum shall as respects potatoes delivered before the 15th April, 1918, be £6, and as respects potatoes delivered between the 15th April, 1918, and 14th May, 1918, inclusive, be £6 10s., and as respects potatoes delivered after the 14th May, 1918, be £7."

2. The following Clause shall be inserted after Clause 2 of the Principal Order :—

"2A. Where, after the 31st March, 1918, a grower of potatoes dresses his clamped potatoes and riddles the same so as to extract therefrom the seed potatoes and re-clamps his ware potatoes, he may make application for payment of a sum of 10s. in respect of each ton of such re-clamped potatoes; provided that a claim shall not be made or allowed under this Clause in respect of a greater quantity of ware potatoes than a quantity which bears the same proportion to the total quantity of ware potatoes extracted from the original clamp as the quantity of seed potatoes extracted and planted or sold for planting by the grower bears to the total quantity of seed potatoes so extracted."

* The Early Potatoes (Prices) Order, 1918: Order No. 554, dated 21st May, 1918.

† Order No. 1183 of 1917. See this *Journal*, December, 1917, p. 1001.

3. The following words shall be inserted at the end of Clause 5 of the Principal Order : " or (iii.) shall have failed to make any return required by or under the authority of the Food Controller or shall have made any false statement in any such return."

AN Order (No. 555), dated 22nd May, 1918, has been made by the Food Controller to the effect that :—

1. All certificates of registration heretofore granted under the Potatoes Order, 1917, by a Food Control Committee in Great Britain to any person as a wholesale dealer shall stand revoked as at 1st June, 1918, so far as the same relate to eating potatoes, and as at the 1st July, 1918, so far as the same relate to seed potatoes.

2. A certificate of registration as a wholesale dealer in potatoes granted or to be granted by the Food Control Committee for Ireland shall not authorise any dealings by such dealer outside Ireland in eating potatoes on or after the 1st June, 1918, or in seed potatoes on or after the 1st July, 1918.

3. Applications for new certificates of registration in Great Britain under the Potatoes Order, 1917, may be made by such persons and in such manner as the Food Controller may from time to time direct. All such certificates shall be subject to such conditions as may be endorsed thereon or as the Food Controller may from time to time prescribe, and shall be revocable by the Food Controller at any time.

4. The holder of any certificate of registration as a wholesale dealer in potatoes shall comply with such directions as to his dealings in potatoes as may from time to time be given by the Food Controller or under his authority.

5. After the date of this Order a Food Control Committee in Great Britain shall not grant to any person a certificate of registration as a wholesale dealer in potatoes.

Mr. Watt : To whom should farmers apply in order to get from the Government the price of £7 10s. per ton for their potatoes in stock after 15th May ?—**Mr. Parker :** The Government have

Potatoes: Questions in Parliament. not indicated any intention of taking over stocks of potatoes from growers on 15th May at £7 10s. per ton ; but, as announced on 29th

March, the Food Controller will be prepared on and after 15th May to purchase all sound ware potatoes in lots of 4 tons at £7 per ton f.o.r., for which the grower cannot otherwise find a market. The returns of stocks just received by the Ministry of Food do not suggest that there will be any substantial surplus of ware potatoes in Great Britain which the growers will be unable to dispose of through the usual trade channels during May and June. If, however, after 14th May any grower has stocks on hand which he sees no prospect of being able to sell for delivery during May or June he should send particulars to the Director of Vegetable Supplies, 100, Cromwell Road, London, S.W. 7, giving the address of his farm and the nearest railway station, together with the names and addresses of any dealers to whom he has unsuccessfully offered to sell his ware potatoes. (7th May.)

Major Wheeler: In view of the scarcity of feeding stuffs for pigs, will the Ministry authorise the sale of small seed potatoes for such a purpose after the requirements of this season's acreage for planting have been met?—**Mr. Clynes:** Any potatoes which are not ware potatoes fit for human consumption may be sold for feeding to pigs without a licence. (9th May.)

Mr. Watt: Is it the intention of the Ministry to pay to farmers possessed of ware potatoes, from 15th May to end of June, the price of £7 per ton f.o.r. in 4-ton lots if they have failed to find purchasers at that price, or are they expected to offer these potatoes to dealers at lower prices than £7 per ton; and, if the latter, is the difference to be made up by the Food Department?—**Mr. Clynes:** Farmers who are able to satisfy the Ministry of Food on and after 15th May that they are unable to find purchasers for their potatoes in lots of 4 tons or more at or above the base price then ruling will be entitled to receive payment for their potatoes from the Ministry of Food at the rate of £7 per ton. If potatoes are sold to dealers at a figure which is below £7 per ton, but not below the current base price, the seller can claim the difference from the Ministry of Food. (9th May.) (*National Food Journal*, 22nd May, 1918.)

THE following Notice was published by the Food Production Department of the Board early in June:—

**Vegetable Marrows
for Jam Making:
Appeal for Increased
Planting.**

Estimates made by the Food Production Department indicate that this year's fruit crops will be insufficient to supply the jam factories with the fruit required for jam-making purposes. In view of the great importance of sufficient supplies of jam being available for use by the Navy and Army, and by the civilian population, the Department is appealing to all cultivators to plant immediately and on as large a scale as possible, vegetable marrows for supplementing the fruit supplies available for the jam factories.

The Department is authorised by the Sugar Commission to announce that there is no prospect of any further allowance of sugar becoming available for the household making of jam from vegetable marrows. Therefore the vegetable marrows grown in response to this appeal should be either sold to jam-making factories or stored for use during the winter.

The Department is informed by the Ministry of Food that thousands of tons of ripened vegetable marrows can be utilised during the coming season by the recognised jam manufacturers.

A leaflet on the cultivation of the vegetable marrow may be obtained free on application to the Food Production Department, 72, Victoria Street, S.W. 1.

THE Orders of the Food Controller relative to the sale of cattle and sheep for slaughter are consolidated in the Live Stock (Sales) Order* which came into force on 13th May. It also

The Live Stock (Sales) Order, 1918. carries out arrangements recently made by the Ministry of Food with the Board of Agriculture and the representatives of the farmers with regard to the sale of cattle and sheep by dead-weight.

* Order No. 517, dated 8th May, 1918.

The Order provides that any beast fit for slaughter or any sheep may, at the option of the vendor with the concurrence of the Live Stock Commissioner, be sold by dead-weight. The dead-weight prices (including the value of the offals) are as follows:—

1. In the case of beasts (other than beasts fit for boning) the sum of 1s. 2½d. per lb.
2. In the case of beasts fit only for boning the sum of 11d. per lb.
3. In the case of sheep the sum of 1s. 2½d. per lb., in addition to the current market value of the skin, less the sum of ½d. per lb. or part of a lb.

“Per lb.” means in each case per lb. of the certified weight of the dressed carcass. The seller of the beasts or sheep will be entitled to a reasonable opportunity of checking the weight of the carcass of any beast or sheep sold by him on the dead-weight system.

The decision of the authorised agent of the Ministry of Food in any market as to whether a beast is fit for slaughter, on the weight and grading of any beast, or on the weight and fair value of any sheep, is final. The conditions for the weighing of the dressed carcass are accurately laid down in order to minimise the possibility of error in determining the just weight. If the authorised person determines that a beast is fit for slaughter it cannot be moved from the market except with his authorisation.

Provision is made for tying farmers to individual markets with a view to regulating supplies and the prevention of unnecessary transport, and as soon as the process of allocation to markets is complete it will be illegal for a stockowner to sell cattle in any other than the prescribed market. Although the provisions of the Order do not apply to Ireland, this Clause will enable the Ministry of Food to determine to which markets Irish fat cattle sent to Great Britain for slaughter shall be allocated. It is also laid down that live stock fit for slaughter may not be moved from one area to another without the consent of the Area Live Stock Commissioner. (*National Food Journal*, 22nd May, 1918.)

THE authorised Government agent in any market has power under the new Live Stock (Sales) Order to determine which cattle are fit for

**Restriction of
Slaughter of Live
Stock.**

slaughter, and instructions have been issued to Grading Committees to exercise their discretion in this matter in view of the fact that stores now at grass will put on weight of flesh during the next few weeks. Fortunately there is in the country at the present moment a sufficient quantity of frozen meat to satisfy rationed requirements. Consequently, it is in the national interest that slaughter should be severely restricted, and that no animal that will benefit by grazing should be brought forward to market. Consumption of frozen meat over a brief period will not only help to conserve and increase home-grown supplies for the autumn, it will release cold storage space for the heavy food imports now coming into the country. Farmers require no incentive to adopt a policy which secures them a better return for their outlay on breeding stock and stores, and consumers, if they once understand the urgency of the situation, will not grudge the small sacrifice involved in the temporary reduction of the proportion of British beef supplied to them. (*National Food Journal*, 22nd May, 1918.)

MR. J. R. CLYNES, M.P., has addressed the following Letter to a correspondent who desired explanation of the Ministry's scheme for the control of cattle and meat :—

**Control of Cattle
and Meat:
Ministry of Food
Scheme.**

The object of the Ministry of Food is to ensure that a fair price shall be paid to the farmer for the meat produced, and to the meat trade for the food as delivered to the consumer. The best way of securing that the farmer is paid in accordance with the exact amount of meat which he produces is to weigh the actual meat produced from the carcass of each beast slaughtered and to pay the farmer accordingly. In view, however, of the difficulties inherent in this system of paying the farmer on the dead-weight basis, Lord Rhondda decided to maintain the present live-weight system save when a majority of the farmers in any locality are willing to sell on a dead-weight basis. Under the live-weight system there is at each authorised market (where alone it is legal for live stock to be sold for slaughter) a grading committee which grades every beast according to the estimated percentage of meat which it will yield. The grading committee consists of one representative each of the farmers and butchers, together with a Government valuer. They express the "grade" of a beast by a figure representing their estimate of the weight of meat to be derived from every 100 lb. of the actual weight of the living animal. Thus a beast which they estimate will yield 56 per cent. of meat or over is placed in Grade 1, one which they estimate will yield as much as 52 per cent. but less than 56 per cent. in Grade 2, and so on. The live beast is weighed, and the farmer is paid at a price per live hundredweight, which is fixed according to the grade in which the beast has been placed; that is to say, according to the quantity (and not the quality) of meat which it is likely to produce. The price per live hundredweight which the farmer is paid for a beast in Grade 1 is 75s., and the price of a beast in Grade 2 is 70s. (and so on), because the former produces a greater weight of meat per live hundredweight; and, if the farmer were paid at the same rate per cwt. for each, he would not be paid for producing more meat.

The graded prices, including the value of offals, are worked out to give the farmer 1s. 2½d. per lb. of the weight of the carcass dressed as it appears entire in the butcher's shop, i.e., per lb. of meat excluding all offals. The wholesale price of the meat is fixed at 1s. 0½d. per lb., and the retail butcher's profit is fixed by the retail selling prices embodied in a schedule of prices for each different joint. This schedule allows the appropriate margin of profit. Owing to the reduced turnover consequent on smaller supplies of meat, the butcher's profits have been cut down, and out of these profits he has to cover all costs of rent, interest and wages. The wholesale and retail prices are fixed uniformly for the whole country and for meat of all qualities irrespective of the grading of the beast from which it comes.

With regard to the shortage of meat, it is common knowledge that last autumn some increased slaughter took place. This was largely due to the freedom of sale and purchase allowed to butchers and farmers, to the short supplies of frozen meat, and to the needs of the Army; but the extra number killed has been much exaggerated. We are now coming to the time when cattle must go on to the grass, and to give an additional supply, or even to keep up the present rate of slaughter of home-grown cattle, might result in the killing of a number of

immature beasts; if these are allowed to remain on the grass during the summer months they will materially add to the available meat supplies.

The policy of the Ministry of Food for the next few months must obviously be to withdraw as small an amount of the live stock as possible, leaving the farmers to a large extent to be the judges in sending forward cattle as they are ready.

It may be pointed out that the whole of the marketing arrangements and many technical details dependent on them have been worked out, and are varied and improved as experience suggests, in close consultation with a strong Central Advisory Committee representative of the farmers' organisations, the Departments of Agriculture and the butchers' and meat trades' organisations and also of the Consumers' Council. The Ministry of Food are very glad to consider on their merits any definite improvements that may be suggested. (*National Food Journal*, 22nd May, 1918.)

THE Food Controller has by general licence* under the Cattle Feeding Stuff (Maximum Prices) Order, 1918,† authorised on a sale of imported

**The Cattle Feeding
Stuff (Maximum
Prices) Order, 1918:
General Licence.**

millers' offals, sold in sacks or bags, a charge for sacks or bags at the rate of 35s. per ton if sold in bags containing 1 cwt. or less, and 25s. per ton if sold in bags containing more than 1 cwt. (*National Food Journal*, 22nd May, 1918.)

THE Food Controller, by an Order (No. 527), dated 13th May, 1918, has made the following Amendment to the Principal Order, No. 1173 of 1917 ‡:—

**Order Amending the
Horse and Poultry
Mixtures Order, 1917.**

1. Clause 3 (b) (iii) of the Principal Order shall be revoked and the following Sub-clause shall be substituted therefor:—

“Where any of the ingredients have been bought by the maker before the 20th May, 1918, and have been mechanically treated before being delivered to the maker's factory, a sum fairly representing the cost of such treatment, except the cost of re-conditioning, shall be deducted in ascertaining the cost. Where any of the ingredients have been bought by the maker on or after the 20th May, 1918, and have been mechanically treated before being delivered to the maker's factory (otherwise than by being reconditioned or rendered more merchantable by kiln-drying or other like treatment) a sum fairly representing the cost of such treatment shall be deducted in ascertaining the cost. Where any of the ingredients have been bought on or after the 20th May, 1918, and have been reconditioned or rendered more merchantable by kiln-drying or other like treatment before being delivered to the maker's factory, the cost of any such

* Order No. 533, dated 15th May, 1918.

ingredients shall not in any case be reckoned at a sum exceeding the maximum price applicable on a sale thereof according to the Damaged Grain, Seeds and Pulse (Prices) Order, 1917, as amended."

An Order (No. 552), dated 21st May, 1918, has been made by the Food Controller to the effect that :—

The Use of Milk 1. Except under and in accordance with the terms of a licence granted by the Food Controller, a person shall not on or after the 17th June, 1918, use any milk, skimmed milk, separated milk, dried milk, condensed milk, butter milk, or any milk preparation in the manufacture for sale of any chocolate, sugar confectionery, or other sweetmeats, or for any other manufacturing purpose except the manufacture of articles intended for human consumption.

2. (a) Except under and in accordance with the terms of a licence granted by the Food Controller, a person shall not on or after the 17th June, 1918, make for sale any condensed milk, dried milk, milk preparation, butter or cheese.

(b) This Clause shall not apply to the making of butter or cheese by a farmer or other producer on the farm where the milk is produced.

3. Except under and in accordance with the terms of a licence granted by the Food Controller, a person shall not, after the 17th June, 1918, sell or offer or expose for sale as milk, or under any description of which the word milk forms part, any liquid in the making of which dried milk or condensed milk had been used.

4. Infringements of this Order are summary offences against the Defence of the Realm Regulations.

5. The Milk Factories (Restriction) Order, 1917, and as respects Great Britain the Milk (Use of Chocolate) Order No. 2, 1917, is hereby revoked as at the 17th June, 1918, but without prejudice to any proceedings in respect of any contravention thereof.

NOTE.—Applications for licences under this Order and correspondence with respect to this Order should be addressed to the Secretary, Ministry of Food (Milk Section), County Hall, Westminster Bridge Road, S.E. 1.

In many districts throughout Great Britain there is for the moment a surplus of farmers' butter, and it is important that all possible steps should be taken to secure that this is put to

Preservation of Surplus Farmers' Butter. the best possible use. Outlets for surplus butter may be found through sales by retailers in the district, and through sales to blenders.

It is not desired that the Food Control Committees should increase the ration of butter and margarine on account of the local surplus, but arrangements are being made under which they will summon meetings of retailers of butter and margarine in their areas and arrange that home-made butter should form as large a proportion as possible for the present of the supplies required to meet the needs of their registered customers—applications for margarine and for imported butter being reduced accordingly. In the case of caterers or institutions buying from wholesalers or direct from the Margarine Clearing House, similar steps should be taken to increase the purchase of home-made butter and to reduce temporarily supplies of imported butter and margarine.

Butter-blending factories exist in a number of districts, principally in the south-western area of England and in South Wales, and no permit is required by farmers desirous of sending butter to blending factories. In all arrangements which may be made for the disposal of surplus butter, it is necessary to secure concerted action between rural areas and adjoining urban areas.

Many householders have in the past been accustomed to buy considerable quantities of butter at this season of the year for salting and preserving for winter use. The Food Controller has issued an authorisation permitting the purchase of farmers' butter for this purpose, provided that application is made to the local Food Committee and permission received from them. Butter will only be supplied for this purpose in cases where the supply is in excess of the ration demand. Applicants will be required to state the quantities it is proposed to salt or preserve and the quantities which have been laid down in this way in the past. In procuring butter for this purpose a certificate must be given to the producer or shopkeeper at the time of purchase stating that it is for preserving. These certificates may be obtained from the local Committee. The quantity applied for may be decreased by the Committee at their discretion. Committees may grant permission of this kind to persons who have not previously been in the habit of preserving butter if this course is justified by circumstances.

The Food Control Committee will fix a date up to which purchases for preserving will be permitted in their district. The date will be fixed to suit local convenience. Butter thus preserved will not be consumed before the same date. Any households preserving butter in this manner will be entitled to consume it subsequently at self-supplier rates, *i.e.*, 6 oz. per member of his household, provided that any regulations as to marking of cards, etc., in the case of self-suppliers are observed.

The Ministry of Food are anxious that surplus milk should be devoted primarily to the manufacture of dried milk and of cheese, and the permission to salt down butter must not be taken as an incentive to produce butter in cases where the production of cheese is possible. A scheme is now under consideration for the collection of British cheese which will enable all producers to dispose satisfactorily of any cheese they may make from the present time onward. Those who propose to make cheese at home will find it useful to secure "Cheesemaking for Small Holders" (Leaflet 231), and "Manufacture of Cheese in Co-operative Dairies" (Special Leaflet 75), issued by the Board of Agriculture. These can be obtained free of charge and post free from the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1. (*National Food Journal*, 22nd May, 1918.)

AN Order (No. 531), dated 14th May, 1918, has been made by the Food Controller to the following effect:—

<p>British Cheese Order, 1917: Notice.</p>	<p>Pursuant to the powers reserved to him by Clause 2 of the British Cheese Order, 1917, as amended,* the Food Controller prescribes the prices set out in the Schedule as the maximum first-hand prices upon all sales made on and after the 18th May, 1918, of cheese as described in the Schedule.</p>
---	---

* Orders Nos. 1105 of 1917, and 386 of 1918. See this *Journal*, November, 1917, p. 910, and January, 1918, p. 1140 respectively.

The Schedule.

Variety of Cheeses.	First-hand Prices for Delivery on and after 18th May, 1918, until further notice.
	Per lb. s. d.
Caerphilly whole milk	1 2½
„ partially skimmed	1 1
„ wholly skimmed	0 11
Any whole milk cheese, not exceeding 2 lb. weight uncut, other than Caerphilly	1 6

Variety of Cheeses.	First-hand Prices for Cheese Manufactured—	
	Before the 11th May, 1918.	On and after 11th May, 1918, until further notice.
	Per lb. s. d.	Per lb. s. d.
Ripened Stilton and Wensleydale (blue)	1 7	1 7½
Dorset—Hand - skimmed blue	1 4½	1 2½
Dorset—separated blue	1 3	1 0½
„ white	1 1½	0 11
All other whole-milk cheese	1 6	1 4
All other partially skimmed cheese	1 3	1 0½
All other wholly skimmed cheese	1 1½	0 11

THE following Regulations, dated 5th April, 1918, have been made by the Board, and became immediately operative :—

1. The Fertilisers and Feeding Stuffs
The Fertilisers and (Methods of Analysis) Regulations, 1908, are hereby amended by the substitution for of Analysis) Provisional paragraph (V.) of Regulation 3 of the following Regulations, 1918. paragraph :—

(V.) *Determination of Potash.*(a) *Muriate of Potash Free from Sulphates.*

A weighed portion of the sample (about 5 grams in the case of concentrated muriate of potash or 10 grams in the case of low-grade muriate) shall be dissolved in water, the solution shall be filtered if necessary and made up to 500 cubic centimetres. The potash shall be determined in 50 cubic centimetres of the solution either by the platinum chloride method, or by the perchloric acid method, prescribed below in Clauses (e) and (f) of this paragraph.

(b) *Salts of Potash containing Sulphates.*

A weighed portion of the sample (about 5 grams in the case of concentrated sulphate of potash or 10 grams in the case of kainit or other low-grade salts) shall be boiled with 20 cubic centimetres of hydrochloric acid and 300 cubic centimetres of water in a half-litre flask. Barium chloride solution shall be cautiously added, drop by drop, to the boiling solution until the sulphuric acid is completely precipitated. Any slight excess of barium shall be removed by the addition of the least possible excess of dilute sulphuric acid. The liquid (without filtration) shall be cooled, made up to 500 cubic centimetres and filtered. Fifty cubic centimetres of the filtrate shall be taken and evaporated to dryness, and shall then be moistened with concentrated hydrochloric acid, again evaporated to dryness, treated with a little dilute hydrochloric acid and filtered, if necessary. The potash shall be determined in the filtrate either by the platinum chloride method, or by the perchloric acid method, prescribed below in Clauses (e) and (f) of this paragraph. If the solution contains phosphates, iron, manganese, or other substances that would interfere with the determination of potash, the method prescribed in Clause (c) of this paragraph is to be used instead of the method prescribed in Clause (b).

(c) *Potash in Flue-Dust.*

Ten grams of the sample shall be gently ignited in order to char organic matter, if present, and shall then be boiled with 300 cubic centimetres of water. Ten cubic centimetres of concentrated hydrochloric acid shall be added slowly so as not to check the boiling which is to be continued for a further 10 minutes after the addition of the last portions of acid. The liquid shall be filtered into a half-litre flask and raised to the boiling point; and to the boiling liquid powdered barium hydroxide is to be added until there is slight excess. The liquid shall then be cooled, made up to 500 cubic centimetres and filtered. Of the filtrate, 250 cubic centimetres shall be treated with ammonia solution and excess of ammonium carbonate, and, while boiling, with a little powdered ammonium oxalate. It shall then be cooled, made up to 500 cubic centimetres and filtered. Of the filtrate, 50 cubic centimetres or 100 cubic centimetres, according to the amount of potash expected, shall be evaporated in a porcelain dish to dryness. If desired, nitric acid may be added during the evaporation after free ammonia has been driven off. The residue is to be heated gently over a low flame until all ammonium salts are expelled, the temperature being carefully kept below that of low redness. The residue shall be moistened with concentrated hydrochloric acid, evaporated to dryness, treated with dilute hydrochloric acid, filtered, and the potash determined in the filtrate either by the platinum chloride method or by the perchloric acid method, prescribed below in Clauses (e) and (f) of this paragraph.

(d) *Potash in Guanos, and Mixed Fertilisers.*

Ten grams of the sample shall be gently ignited in order to char organic matter, if present, and shall then be heated for 10 minutes with 10 cubic centimetres of concentrated hydrochloric acid, and finally boiled with 300 cubic centimetres of water. The liquid shall be filtered into a half-litre flask, raised to the boiling point, and a slight excess of powdered barium hydroxide shall be added. The contents of the flask shall be cooled, made up to 500 cubic centimetres and filtered. Of the filtrate, 250 cubic centimetres shall be treated with ammonia solution

and excess of ammonium carbonate, and then, while boiling, with a little powdered ammonium oxalate, cooled, made up to 500 cubic centimetres and filtered. Of the filtrate, 100 cubic centimetres are to be evaporated in a porcelain dish to dryness. If desired, nitric acid may be added during the evaporation after free ammonia has been driven off. The residue is to be heated gently over a low flame, till all ammonium salts are expelled, the temperature being carefully kept below that of low redness. The residue shall be moistened with concentrated hydrochloric acid, evaporated to dryness, treated with dilute hydrochloric acid and filtered. The potash shall be determined in the filtrate either by the platinum chloride method, or by the perchloric acid method, prescribed below in Clauses (e) and (f) of this paragraph.

(e) *Platinum Chloride Method.*

To the solution obtained as above described in Clauses (a), (b), (c) or (d) of this paragraph a few drops of hydrochloric acid shall be added, if none is present, and also 10 or 20 cubic centimetres (according to whether the portion weighed was 5 grams or 10 grams) of a solution of platinum chloride containing 10 grams of platinum per 100 cubic centimetres. After evaporation to a syrupy consistency on a water-bath, the contents of the basin shall be allowed to cool and shall then be treated with alcohol of specific gravity 0.864, being washed by decantation until the alcohol is colourless. The washings shall be passed through a weighed or counterpoised filter paper, on which the precipitate shall be finally collected, washed with alcohol as above, dried at 100° C. and weighed.

The precipitate is to be regarded as K_2PtCl_6 , and is to be calculated to its equivalent as K_2O .

(f) *Perchloric Acid Method.*

To the solution obtained as above described in Clauses (a), (b), (c) or (d) of this paragraph and placed in a small glass or porcelain basin, 7 cubic centimetres, or 12 cubic centimetres (according to whether the portion weighed was 5 grams or 10 grams) of a 20 per cent. solution of perchloric acid (specific gravity 1.125) shall be added. The basin shall be placed on a hot plate or sand bath and the contents evaporated until white fumes are copiously evolved. The precipitate shall be re-dissolved in hot water, a few drops of perchloric acid solution added, and the whole concentrated again to the fuming stage. After cooling, the residue in the basin shall be thoroughly stirred with 20 cubic centimetres of alcohol of specific gravity 0.816 to 0.812 (95 to 96 per cent. of alcohol by volume). The precipitate shall be allowed to settle, and the clear liquid shall be poured through a weighed or counterpoised filter paper, or through a gouch crucible, draining the precipitate as completely as possible from the liquid before adding the washing solution. The precipitate shall be washed by decantation with alcohol (as above) saturated with potassium perchlorate at the temperature at which it is used, pouring the washings through the paper or gouch crucible on which the whole of the precipitate is finally collected, dried at 100° C., and weighed.

The precipitate is to be regarded as $KClO_4$, and is to be calculated to its equivalent as K_2O .

2. Nothing herein contained shall affect an analysis made before the commencement of these Regulations or the validity of any certificate of an analysis so made or any legal proceedings in respect of any sample to which any such analysis or certificate relates.

THE following Notice (F.P. 266), dated 4th May, 1918, has been issued by the Food Production Department of the Board :—

Under the Fertiliser Prices Order, 1918.*

Maximum Prices of maximum prices are fixed for the sale of the **Sulphate of Ammonia**, above fertilisers, as from 1st June, 1918, to **Superphosphate and** 31st May, 1919. These prices are, on the **Ground Basic Slag:** average, the same as those ruling in 1917-18, **Season 1st June, 1918—** except that in the case of basic slag a small **31st May, 1919.** increase of price is made to cover increased cost of manufacture. Basic slag is to be sold in 1918-19 at a delivered price based on the percentage of total phosphates contained in the basic slag, without reference to citric solubility.

The following summary sets out shortly for the information of purchasers the effect of the main provisions of the Order in regard to the prices of fertilisers, but should any doubt exist or dispute occur, reference must be made to the Order itself, copies of which may be obtained from the Food Production Department.

The Order also prescribes the arrangements for distributing the fertilisers throughout the country, and makers, merchants, dealers and co-operative societies should familiarise themselves with these arrangements, which are dealt with in Food Production Notice No. 254.†

1. Basis Prices.—The basis prices are the maximum net cash prices for sulphate of ammonia, superphosphate and ground basic slag, in makers' 2-cwt. bags, delivered in railway truck or free *ex* barge or ship at purchaser's or consumer's siding, railway station or wharf anywhere in the United Kingdom, or (in the case of basic slag) anywhere in England Scotland or Wales and c.i.f. Irish Ports. Such basis prices are as follows :—

SULPHATE OF AMMONIA.

- (a) For sulphate of ammonia, containing $24\frac{1}{2}$ per cent. ammonia, sold for delivery in the periods shown below, the basis prices are :—

<i>Date for Delivery.</i>	<i>Price.</i>			
	£	s.	d.	
1st June—31st August, 1918	15	5	0	per ton.
1st September—30th November, 1918	15	15	0	..
1st December, 1918—28th February, 1919	16	5	0	..
1st March—31st May, 1919	16	15	0	..

- (b) For sulphate of ammonia containing more than $24\frac{1}{2}$ per cent. of ammonia, the maximum prices are increased by 3s. 3d. per ton for each complete quarter per cent. above $24\frac{1}{2}$ per cent., whilst for sulphate of ammonia falling below $24\frac{1}{2}$ per cent. a corresponding reduction in price must be made, except that in this case fractions of $\frac{1}{4}$ per cent. are to be taken into account.

An additional charge (not exceeding 5s. per ton) may be made for sulphate of ammonia containing less than .025 per cent. of free acid. The object of this charge is to encourage makers to produce sulphate of ammonia in the best possible mechanical condition.

* See this *Journal*, May, 1918, p. 221.

† Not here printed. Copies may be obtained on application to the Fertilisers Allocation Joint Committee, 72, Victoria Street, S.W. 1.

Where a purchaser requires sulphate of ammonia to be specially ground or pulverised, an extra charge of 5s. per ton may be made.

The above increases and deductions do not apply to sales of less than 2 cwt.

SUPERPHOSPHATE.

The basis prices for any grade of superphosphate may be calculated by taking as a basis the price of £6 10s. for 30-31 per cent. water soluble sold for delivery during December, 1918. The price for superphosphate of this grade sold for delivery during other months will be 1s. 6d. per ton less for each month from July to December, and 1s. 6d. per ton more for each month subsequent to December, with a maximum decrease or increase of 7s. 6d. per ton. For example, the price for 30-31 per cent. for delivery in July, 1918, will be £6 2s 6d., and for delivery during May, 1919, will be £6 17s. 6d. The price for June, 1918, deliveries remains, however, as fixed by the Superphosphates Order, 1917, i.e., £6 15s. per ton.

For other grades the price decreases by 2s. 6d. for each complete unit of water soluble phosphates below 30 per cent., and increases by 4s. for each complete unit above 30 per cent.

The table on p. 360 shows the prices of the grades most commonly sold.

GROUND BASIC SLAG.

- (a) For ground basic slag sold for delivery during the period 1st September, 1918, to 28th February, 1919, the basis prices are :—

<i>Percentage of Total Phosphate (calculated in terms of Tribasic Phosphate of Lime.)</i>			<i>Price per ton.</i>
12	60s.
14	62s.
16	64s.
18	66s.
20	68s.
22	70s.
24	73s.
26	76s.
28	79s.
30	82s.
32	85s.
34	88s.
36	91s.
38	94s.
40	97s.
42	100s.

- (b) In the case of sales of ground basic slag for delivery during other months the maximum prices for all qualities will be less than the prices set out above, in accordance with the following table :—

<i>Month for Delivery.</i>			<i>Reduction in Maximum Price set out above.</i>	
June	1918	4s.	per ton.
July	"	3s.	"
August	"	2s.	"
March	1919	2s.	"
April	"	3s.	"
May	"	4s.	"

- (c) The foregoing prices for all qualities are for basic slag ground in such a way that at least 80 per cent. will pass through a sieve containing 10,000 holes to the square inch. If the slag sold be less finely ground, an allowance must be made to the purchaser at the rate of 3d. for each 1 per cent. by which the quantity which will pass through the sieve is less than 80 per cent., but where the quantity which will pass through the sieve is less than 75 per cent. an additional allowance must be made to the purchaser at the rate of 9d. for each 1 per cent. by which the quantity passing through the sieve is less than 75 per cent. : e.g., where the percentage passing through the sieve is 75 per cent., a reduction at the rate of 1s. 3d. per ton is to be made, but where the percentage passing through the sieve is only 70 per cent., the reduction will be at the rate of 6s. 3d. per ton.
- (d) An additional charge at the rate of 2s. 6d. per ton may be made for basic slag packed in special bags for carriage by sea.

II. Prices other than Basis Prices.—The Order prohibits sales or purchases of any of the three fertilisers for delivery at maker's works or nearest railway station or wharf, where the fertiliser is to be transported by rail or water. The following sales are, however, authorised, at the prices mentioned below, namely :—

- (a) *Sales for delivery at maker's works for conveyance direct by road to purchaser's or consumer's premises.*—The price for such sales is 10s. per ton less than the basis price, the purchaser or consumer providing the cart or other vehicle. If the maker provides the vehicle, the purchaser or consumer may be charged by the maker the cost of carting from the works to purchaser's or consumer's premises at not more than local rates. In all cases where the purchaser is not the consumer, it will be necessary for the maker to obtain a licence before effecting the sale.
- (b) *Sales for delivery ex railway goods yard or public wharf.*—The maximum price for such sales is 2s. 6d. per ton in excess of the basis price, except that no addition to the basis price is to be made in the case of sales of more than 1 ton.
- For example, in the case of a truck load being consigned to a dealer at one station and re-sold in 6 1-ton and 1 2-ton lots, an extra charge of 2s. 6d. per ton over the basis price may be made by the dealer on each of the 6 1-ton lots, but no extra charge may be made on the 2-ton lot.
- (c) *Sales for delivery ex vendor's store or shop or ex warehouse.*—The maximum prices for such sales are the basis prices, with the following additions according to the quantity of fertiliser purchased :—

	s.	d.
1 ton and over	10	0 per ton.
2 cwt. and over but less than 1 ton. ..	1	0 per cwt.
1 " " " 2 cwt. ..	2	0 " "
28 lb. " " 1 " ..	3	0 " "
14 " " " 28 lb. ..	4	0 " "

For example, taking the basis price of 30-31 per cent., superphosphates in December at £6 10s. per ton, the price for sales by merchants or dealers *ex store* will be :—

				£	s.	d.	
1 ton and over	7	0	0	per ton.
2 cwt. but less than 1 ton	0	7	6	per cwt.
1 "	"	2 cwt.	..	0	8	6	"
28 lb.	"	1 cwt.	..	0	9	6	"
14 "	"	28 lb.	..	0	10	6	"

In addition, where the vendor's store or shop is more than 2 miles from the nearest railway station or wharf, the vendor must bear the cost of carting the fertiliser from the station or wharf to his shop in all cases for a distance of 2 miles, but may charge the extra cost involved in carting it a greater distance.

- (d) *Sales for delivery direct by road or barge from vendor's shop or store, or from warehouse, railway goods yard or public wharf to consumer's premises.*—The maximum prices for such sales are the same as those for sales or delivery *ex* such shop, store, warehouse, goods yard or wharf, plus the cost of cartage or barging to the consumer's premises.

III. **Authorised Variations in Price.**—The following variations in the above prices are authorised or prescribed by the Order :—

- (a) *Small Sales by Makers.*—Makers selling any of the three fertilisers in smaller quantities than 2 tons may charge the retail prices set out under II. (c) and (d) above in all cases, except where the sale is for delivery *ex* railway goods yard or public wharf.
- (b) *Credit Sales.*—Where credit is given to the purchaser, a reasonable extra charge may be made, but the discount allowed for net cash must be quoted on the invoice given to the purchaser and must be such as to bring the net cash price down to the maximum price authorised.
- (c) *Bags.*—On sales of 1 ton or more for delivery in bags containing less than 2 cwt. each, a reasonable extra charge may be made, whilst where purchaser's bags are used, or the purchaser takes delivery in bulk, a reasonable allowance must be made to the purchaser.

IV. **Small Consignments by Rail.**—The Order prohibits, except under special licence to be obtained by the seller, consignments of less than 4 tons by rail, and such licences will only be issued in quite special circumstances. Accordingly, persons whose requirements for delivery at any time are less than 4 tons, should either purchase from local dealers, or else arrange with neighbours to make up a total order of 4 tons or over for delivery to their nearest station.

Makers will be instructed to give priority to orders for full truck loads.

V. **Existing Contracts Unaffected.**—The Order does not rescind or affect any contracts entered into previously to 1st May, 1918, even though the fertiliser is to be delivered after the 31st May. Copies of the Order may be obtained from the Food Production Department, 72, Victoria Street, S.W. 1.

VI. **Important Notice to Farmers.**—*Approved Fertiliser Agents.*—The Food Production Department is appointing as " Approved Fertiliser Agents " agricultural merchants, dealers, and co-operative societies in each county in England and Wales. These agents are required to store

quantities of superphosphate, sulphate of ammonia, and basic slag, more especially to meet the demands of allotment holders and small growers. It is important to note that the storage of fertilisers by approved agents is not intended to take the place of the immediate ordering by farmers of their full year's requirements.

Farmers should place orders with these agents or with the merchants or co-operative societies from whom they usually obtain supplies, but in the event of their being unable to purchase through these sources they should communicate with the Food Production Department (Supplies Division), 72, Victoria Street, London, S.W. 1.

Orders to be placed at once.—The supplies of these fertilisers are not likely to be enough to meet all demands. The sliding scales of prices are designed to make it worth the farmer's while to take early delivery, and it is only by so doing that he can make sure of obtaining his supplies.

THE following Notice was issued by the Food Production Department of the Board on 6th May :—

Appointment of Approved Agents for the Sale of Fertilisers in England and Wales, 1918-19. 1. The Fertiliser Prices Order, 1918, fixes the prices of superphosphate, sulphate of ammonia, and basic slag, and also provides for the control of distribution by the Agricultural Departments. The growing difficulties of railway transport, due to the shortage of wagons and sheets, have made it necessary for the Department to regulate both sales and deliveries of these fertilisers in order to ensure that the available supply shall be distributed so as to secure the maximum production of food. Information as to the system of licensing which is compulsory on all makers is given in a separate Circular, F.P. 254, but the Department also proposes to appoint approved agents for the sale of fertilisers in each county in England and Wales as a supplementary means of promoting local distribution and storage.

2. These approved agents will comprise merchants, dealers, and co-operative societies (including makers carrying on a retail trade) who undertake :—

(a) To store, before 31st August in the case of sulphate of ammonia, and before 30th September in the case of superphosphate and basic slag, on their own premises or on premises hired for the purpose, a quantity, representing not less than one-tenth of the total quantity of these fertilisers to be purchased during the year, June, 1918, to May, 1919.

(b) To maintain this minimum quantity in store, replacing it as sold throughout the season, until 15th February, 1919, and one-half of this quantity (*i.e.*, one-twentieth of the total for the twelve months) from 15th February to 15th April, 1919, except in the case of basic slag, which need not be stored after 15th February.

(c) To maintain a stock of and to undertake to sell these fertilisers in 14 lb., 28 lb., 56 lb., and 1 cwt. lots, as required to meet the needs of allotment holders and small growers in the approved agent's district, especially between 1st January and 15th April, 1919.

Note.—Under the above arrangement an approved agent whose average total annual sales amounted to 150 tons of sulphate of ammonia,

200 tons of superphosphate, and 150 tons of basic slag, would keep in stock until 15th February, 1919, not less than 15 tons of sulphate of ammonia, 20 tons of superphosphate, and 15 tons of basic slag, replacing quantities sold from time to time, and one-half the above amounts of sulphate of ammonia and superphosphate during the subsequent two months.

3. Priority in the allocation of supplies will, as far as possible, be given to approved agents complying with the above conditions, though the Department will only be in a position to do this in respect of definite applications received before 18th May, 1918. An endeavour will, however, be made throughout the year to meet the needs of approved agents provided their requirements are notified to the Department sufficiently in advance.

4. The Department will publish on or about 15th September, 1918, for supply to Agricultural Executive Committees and for circulation to farmers and allotment holders, lists of names and addresses of those approved agents in each county who have undertaken to store not less than 10 tons of sulphate of ammonia and quantities of superphosphate and basic slag proportionate to their annual purchases. Approved agents will also be entitled to describe themselves as "Approved Fertiliser Agents of the Food Production Department."

5. The undertaking that not less than 10 per cent. of their annual purchases will be stored on their own premises, or on premises hired for the purpose, for local sale throughout the season must be regarded as binding, and the name of any firm which fails to comply with this undertaking will be struck off the list.

6. Approved agents having premises in more than one county can be recognised in respect of each county, but in such cases they must undertake to store 10 per cent. of their purchases for delivery in each of the counties. A separate application should be made in respect of each county.

7. The Fertiliser Prices Order, in addition to a sliding scale of prices according to date of delivery, allows increased charges for sales from store, shop or warehouse, and the Department is advised that these two allowances taken together are sufficient to cover the cost of storage and to allow a reasonable profit to merchants.

8. Licences to sell blast furnace flue-dust and other forms of potash (if available) will only be issued to approved agents, but there is no obligation to store these materials. Approved agents who receive licences will, however, be expected to store sufficient quantities to meet the needs of allotment holders.

9. If it should subsequently be necessary to appoint selected dealers for the distribution of seeds or other agricultural supplies, the approved agents will not necessarily be appointed, though their applications will receive careful consideration.

10. The conditions which applied to the appointment of approved agents during the season 1917-18 in regard to the storage of sulphate of ammonia are cancelled, and such agents must make fresh application in accordance with the new conditions.

11. The names of firms applying to be appointed as approved agents will be submitted to the Supplies Sub-Committees of the County Agricultural Executive Committees, and the Supplies Sub-Committees will be asked to satisfy themselves from time to time that the approved agents are carrying out their obligations.

12. The Department has sanctioned the formation in each county by the National Association of Corn and Agricultural Merchants (Head Office: 16, Mark Lane, London, E.C. 3) of an Advisory Committee of merchants, upon which the local Agricultural Co-operative Societies will also be represented. It is desirable that the approved agents shall keep in touch with the secretaries of the Advisory Committees of Merchants, who will be able to give them advice and inform them as to the detailed working of the distribution scheme.

13. Merchants, dealers and co-operative societies wishing to become approved agents should make application to the Food Production Department before 18th May, on the prescribed form F.P. 265, stating the quantity of sulphate of ammonia, superphosphate, and basic slag they are prepared to purchase and the quantity they will keep in stock, i.e., stored on their own or hired premises to meet local needs.

14. Orders for superphosphate for delivery by 31st August should be placed with the maker at the same time as the application is made. Makers of basic slag should also be notified of the quantity which the approved agent desires to purchase on an annual contract. The requirements of sulphate of ammonia will be dealt with direct by the Department, and the approved agent informed of the maker from whom he can obtain supplies.

Merchants should note that no maker will be licensed to supply superphosphate or ground basic slag to destinations involving a through rate for transport of more than 12s. 6d. per ton or in the case of sulphate of ammonia of more than 5s. per ton without the special permission of the Department.

THE following Notice was issued by the Food Production Department towards the end of May :—

**Fertiliser Supplies:
Urgent Warning
to Farmers.**

Farmers are urged by the Food Production Department to give immediate attention to the question of their supplies of fertilisers for next season. There is an extreme likelihood of an unavoidable shortage of sulphate of ammonia, superphosphate and ground basic slag, and only those farmers who order early are likely to secure their supplies in full and in good time. The Department is appointing as approved fertiliser agents a large number of agricultural merchants, dealers, and co-operative societies in each county of England and Wales. These agents are required to store quantities of sulphate of ammonia, superphosphate and basic slag. But this storage is intended more especially to meet the demand of allotment holders and small growers. It is not intended to take the place of an immediate order by farmers for their full year's requirements. Farmers, therefore, should place orders without delay with the approved agents or with such other merchants, dealers, or co-operative societies as usually supply them. A sliding scale of prices makes it well worth the farmer's while to order early and take early delivery. If for any reason a farmer should find difficulty in purchasing through his ordinary sources of supply he should communicate immediately, giving all necessary details, with the Food Production Department (Supplies Division), 72, Victoria Street, London, S.W. 1, from whom also he can obtain free a copy of the Department's General Notice to Farmers giving particulars as to the maximum prices for sulphate of ammonia, superphosphate, and basic slag for the season 1st June, 1918,

to 31st May, 1919.* The prices, it may be mentioned, are fixed under the Fertiliser Prices Order, 1918. On the average they are the same as those ruling in 1917-18, except as to basic slag, the price of which is slightly increased for next season. The slag is to be sold in 1918-19 at a delivered price on the percentage of total phosphates without reference to citric solubility. Owing to the need of economising railway transport farmers must accept whatever grade of slag is offered to them by their suppliers.

ACCORDING to a Notice issued by the Food Production Department on 27th May, reports received by the Department showed that fruit

trees were suffering from bad attacks of
Caterpillar Attacks ; caterpillar in many districts. Fruit growers
Arsenate of Lead were urged to spray their trees without delay
Spraying. with a solution containing $\frac{1}{2}$ lb. of lead arsenate

paste to every 10 gal. of water. This spray-
 fluid if applied properly will kill the caterpillars and prevent further
 defoliation. The application should be made in a fine spray sufficient
 to wet the leaves without drenching them.

Care must be taken that no vegetables or green gooseberries grown in the neighbourhood of the sprayed trees are gathered for consumption within a month of the application, as lead arsenate is a very poisonous chemical ; nor must trees in full bloom be sprayed, as otherwise bees and other insects useful in pollinating flowers may be killed.

Food Production Leaflet No. 32 gives full information as to the control of both caterpillars and aphides ; it may be obtained free of charge on application to the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London. S.W. 1.

AN Order (No. 521), dated 10th May, 1918, has been made by the Food Controller to the effect that :—

The Beehive Section 1. A person shall not on or after the 13th
(Maximum Prices) May, 1918, sell or offer to expose for sale or
Order, 1918. buy or offer to buy 1 lb. beehive sections of a
 description or quality set out in the Schedules
 to this Order at prices exceeding the maximum
 prices applicable thereto according to the provisions of this Order.

2. The maximum prices shall be as follows :—

(a) On the occasion of a wholesale sale at the rates set out in the First Schedule to this Order ; and

(b) On the occasion of a retail sale at the rates set out in the Second Schedule to this Order.

3. On the occasion of any sale —

(a) No charge may be made for boxes, packages, or packing or for giving credit ;

(b) The price is a price ~~ex~~ seller's premises, and all cost of transport from such premises shall be for the buyer's account.

4. A person shall not in connection with the sale or disposition, or proposed sale or disposition, of any beehive sections to which this Order applies enter or offer to enter into any artificial or fictitious transaction or make or demand any unreasonable charge.

* See p. 359.

5. For the purposes of this Order—

The expression "wholesale sale" shall mean the sale of any quantity to a person buying for the purpose of re-sale.

The expression "retail sale" shall mean any sale other than a wholesale sale.

First Schedule.

MAXIMUM PRICES ON WHOLESALE SALES.

THE following announcement with reference to Farmers' Income Tax for the year ending 5th April, 1919, was made by the Board on 15th May, 1918 :—

**Farmers and
Income Tax.**

1. The new Budget proposals provide that the profits of a farmer assessed under Schedule B shall be reckoned as equal to twice the full rent or annual value of the land which he farms. This means that if the proposals become law, a farmer who was liable to Income Tax in 1917 will be called upon to pay in January and July, 1919, on an assessed profit which will be double that on which he paid in

January and July, 1918; whilst a large number of farmers who have hitherto been exempt from Income Tax will now become liable.

2. A farmer, however, has the right to elect to be assessed under Schedule D instead of under Schedule B. In order to be so assessed he must give notice to the Surveyor of Taxes before 5th June, 1918. The assessment under Schedule D must be based on the average of his profits for the three years, 1915, 1916 and 1917.

3. Although a farmer does not elect to be assessed under Schedule D he will not be bound to pay the tax assessed under Schedule B on twice his rental value *if he can prove that he has not made that amount of profit*. He can give notice to the Surveyor of Taxes at the end of his farming year and claim to pay on the actual profit which he can prove he has made.

4. *Both in the case of an assessment under Schedule D and in the case of an appeal against an assessment under Schedule B at the end of the year the production of accounts will be necessary.*

5. These accounts may be kept in the simplest possible form provided that they give the following particulars:—

I. The value of the live stock, implements, corn, hay, straw and other produce; seeds, manures and other stores, at the beginning of the year and again at the end of the year.

II. The payments made during the year for rent, rates, purchases of stock, feeding-stuffs, manures and other outgoings incurred in carrying on the farm.

III. The receipts during the year from the sale of stock, corn or other farm produce, together with an estimate of the value of the farm produce (meat, poultry, eggs, etc.) consumed by the farmer and his family.

IV. The farm debts owing to and by the farmer at the beginning of the year and at the end of the year.

The value of stock, etc., and the debts owing to the farmer at the beginning of the year, together with the year's expenditure, will form the debit side of the account after deducting the debts owing by the farmer at the beginning of the year.

The value of the stock, etc., and of the debts owing to the farmer at the end of the year, together with the year's receipts, will form the credit side of the account after deducting the debts owing by the farmer at the end of the year.

The excess of the credit side over the debit side will give the year's profit.

6. Properly the valuation at the beginning and end of the year should include, besides live and dead stock, the tillages, growing crops, unexhausted manures, etc. The Income Tax authorities are, however, prepared to accept an account that does not contain these latter items provided that the farmer can certify that the valuation has not materially altered during the year, or that he can give particulars of any increase or decrease which has taken place.

7. The farmer should therefore remember that, although he will have to pay in January, 1919, one-half of the amount of the tax assessed upon him under Schedule B, he will be able, as soon as his farming year is ended and he has his accounts ready, to claim to pay tax only on his actual profits.

If his claim is admitted by the Income Tax authorities his exact liability will be determined and adjusted before the second instalment of the tax falls due on the 1st July, 1919, and he will get a rebate of any part of the tax paid in January, 1919, which proves to have been overcharged.

8. As those farmers who have not hitherto kept accounts would be unable to render an account for the year ending on or before 5th April, 1919, the Board of Inland Revenue will, if such farmers start to keep accounts now, accept a statement of account for the year ending on 1st June, 1919.

9. The farmer who has not hitherto kept accounts must begin to do so before the 1st June if he is to take advantage of the provision that enables him to pay Income Tax on his profits instead of his double rent. He should begin at once to make an inventory of the live and dead stock on the farm, entering all the items in a book and putting the values opposite each. He should buy one of the simple farm account books which can be obtained as a rule from any country stationer, and from 1st June enter in it the payments he makes and the monies he receives according to the instructions he will find therein.

10. It is also desirable that farmers who have not a banking account at present should open one, as their bank pass-books might be of use to them in substantiating a claim for reduction of their assessment.

11. A farmer whose total rent does not exceed £65 a year, and who has no other source of income whatever, will be exempt from Income Tax.

Copies of this announcement can be obtained on application to the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1.

THE Agricultural Wages Board (England and Wales) have fixed the following minimum rates of wages for male workmen of 18 years of age and over employed in agriculture for time-work in the area comprising the administrative counties of Northampton and Soke of Peterborough and the county boroughs of Northampton, that is to say:

**New Minimum
Rates of Wages
for Male Workmen
in Northamptonshire.**

1. The wages payable for employment in Summer (as hereinafter defined) of male workmen in agriculture of 18 years of age and over, shall be not less than wages at the minimum rate of 30s. for 54 hours (exclusive of meal times).

2. The wages payable for employment in Winter (as hereinafter defined) of male workmen in agriculture of 18 years of age and over, shall be not less than wages at the minimum rate of 30s. for 48 hours (exclusive of meal times).

3. The above minimum rates shall apply to all male workmen of 18 years of age and upwards who are wholly or partly employed in agriculture within the meaning of Section 17 (1) of the Corn Production Act, 1917, in the above-mentioned area during such time as they are so employed.

4. For the purpose of the above minimum rates employment in Summer shall be deemed to be employment during the period commencing on the first Monday in March and terminating on the last Sunday in October; and employment in Winter shall be deemed to be employment during the rest of the year.

5. The above minimum rates shall come into operation on the 27th day of May, 1918.

THE Meteorological Office will, as in past years, but subject to certain restrictions, supply forecasts of weather by telegraph to persons desirous of receiving them, upon payment of a registration fee of 1s. and the cost of the telegrams, computed at 9d. per day. The supply of forecasts will continue until 30th September. The forecasts are drawn up each week-day at 4.30 p.m.,

**Harvest Weather
Forecasts.**

and refer to the probable weather during the 15 hours from 6.0 a.m. to 9.0 p.m. on the next day. The addition of a "further outlook" and the issue of notifications in connection with spells of settled weather are suspended during the War.

Applications for the forecasts should be sent to the Director, Meteorological Office, South Kensington, London, S.W. 7, with a cheque or postal order payable to the Meteorological Committee, to cover the cost of the telegrams for the period, which should not be less than six consecutive days, during which the forecasts are to be sent.

THE attention of the Ministry of Food has been drawn to a statement which has recently appeared in the Press to the effect that certain shopkeepers are selling broken Army biscuits

Illegal Dog-Feeding. to be used for feeding dogs.

The Ministry point out that the use of these biscuits for purposes other than human food is in contravention of the Wheat, Rye and Rice (Restriction) Order, 1917,* and that any person having knowledge of such use should communicate the facts to the Ministry of Food (Enforcement Branch), 18, Upper Grosvenor Street, W. 1, or to his Food Control Committee. (*National Food Journal*, 22nd May.)

MISCELLANEOUS NOTES.

THE *International Crop Report and Agricultural Statistics* for May, 1918, issued by the International Institute of Agriculture, contains particulars concerning the sowing of winter

Notes on Crop Prospects Abroad. cereals in the Northern Hemisphere. The areas estimated to have been sown with *wheat* in 1917-18, compared with the areas sown

during the corresponding period of 1916-17, expressed as percentages, are as follows:—Denmark 102, Spain 99, France 107, England and Wales 115, Scotland 122, Luxemburg 105, Canada 88, United States 105, British India 105, Japan 118, Tunis 115; with *rye*:—Denmark 118, Spain 109, France 96, England and Wales 103, Luxemburg 95, United States 145; with *barley*:—Spain 111, France 92, England and Wales 100, Japan 99, Tunis 145; with *oats*:—Spain 129, France 106, England and Wales 100, Tunis 117.

France.—According to an official report on the agricultural position, dated 1st May, 1918, April was generally wet and cold, and consequently field work has been delayed and vegetation is backward. Crops and pastures, however, look well, and the planting of potatoes and root crops is well forward. The frosts have done some harm not only to vines, but to various fruit trees, especially apricots, peaches and plums (*Journal Officiel de la République Française*, 6th May, 1918.)

Canada.—According to a report issued on 14th May, by the Census and Statistics Office, the area of winter wheat sown, viz., 711,000 acres, was reduced to 348,670 acres through winter killing, and the condition of the crop on 30th April indicates a yield per acre only 71 per cent.

* See this *Journal*, May, 1917, p. 236.

of the average for the past nine years. Spring seeding has made excellent progress, the proportion of spring wheat seeded by 30th April being 66 per cent. (13 per cent. last year), of oats 24 per cent. (12 per cent. last year) and of barley 20 per cent. (9 per cent. last year).

United States.—According to a report issued on 7th June by the Statistician of the Department of Agriculture the condition of crops on 1st June was estimated as follows :— Winter wheat, 83·8 per cent. compared with 70·9 a year ago, with a probable yield of 587,000,000 bush. as against 418,000,000 bush. last year ; spring wheat 95·2 per cent., compared with 91·6 last year, with a probable yield of 344,000,000 bush. as against 232,000,000 bush. last year. The average condition of oats on 1st June was 93·2 per cent. as against 88·8 a year ago, the yield being estimated at 1,500,000,000 bush. as against 1,587,000,000 bush. last year. The condition of barley was estimated at 90·5 per cent. as against 89·3 last year, with a probable yield of 235,000,000 bush. compared with 209,000,000 bush. last year. Rye was placed at 83·6 per cent. against 84·3 a year ago, with an estimated crop of 81,000,000 bush. as against 60,000,000 finally returned last year. (*Broomhall's Corn Trade News*, 8th June, 1918.)

India.—According to the final official forecast the yield of wheat in India for the season 1917–18 is estimated at 47,525,000 qr. as against the previous estimate of 47,960,000 qr. Last year's yield was 47,413,000 qr. The surplus available for export, apart from reserves from 1917, is 8,500,000 to 9,000,000 qr. The total linseed crop is estimated at 507,000 tons from 3,737,000 acres as against a corresponding estimate last year of 520,000 tons from 3,533,000 acres. The total yield of rape seed is estimated at 1,111,000 tons from 6,884,000 acres as against last year's estimate of 1,186,000 tons from 6,507,000 acres. (*The London Grain, Seed and Oil Reporter*, 4th and 7th June, 1918).

Australia.—According to reports from the Weather Observers of the Commonwealth Meteorology Department, conditions during February were on the whole favourable. Rainfall was excessive in some parts and seriously deficient in others, but grass was plentiful even where rather dry, and stock were in good condition except in a few places where the drought had been serious. Harvest was practically completed, and the general yield seemed fairly good, though reports varied greatly. Fruit was good on the whole and the vintage season promising.

THE Crop Reporters of the Board, in reporting on agricultural conditions in England and Wales on the 1st June, state that May was generally a very favourable month, the increased warmth and sufficient rains bringing

**Agricultural
Conditions in England
and Wales
on 1st June.**

the crops on well. In some few areas the month was too dry, and rain would now be welcomed in most parts for the corn crops.

Wheat is mostly looking well, but some of the spring-sown on newly-ploughed grass land has been damaged by wireworm or leather-jackets. Oats suffered more from these pests on newly broken-up pasture, and re-sowing has in several cases been necessary. On old arable land the crops are strong and healthy ; and generally they may be described as satisfactory. Barley is also a

satisfactory crop. Beans are good, as are also peas. The area under barley is rather greater than last year; that under oats is larger than a year ago by nearly a fourth.

Potatoes generally present a satisfactory appearance, and are of good promise. In many areas planting was late, and the main crop is not yet everywhere above ground. The area under this crop is fully 20 per cent. greater than last year.

Mangold sowing was completed under favourable conditions, and the crop is coming up well. In many districts, however, damage is reported from insect pests, and some re-sowing has had to be done. Turnip sowing is going on under satisfactory conditions, but in many districts farmers are waiting for rain. The early-sown crops have been frequently attacked by turnip fly.

Hops developed well during the month, but are still backward in Kent. Aphis attacks are prevalent in all districts, and washing is general; but the crop is otherwise satisfactory, and, if the fly can be kept under, may be considered promising. The area is rather less than last year.

The prospects for all orchard fruit are very poor, particularly plums (which were badly cut by frost) and pears. Bush fruits are decidedly better; strawberries should be about average, raspberries over average; while currants and gooseberries are rather under normal.

The area intended for hay, whether from seeds or meadow, is decidedly less than last year, by nearly 10 per cent. Prospects are good, however, nearly everywhere, and both kinds are expected to yield a little over average; the best reports coming from the eastern counties.

With the warmer weather, and consequent growth of grass, live stock have made good progress during the month, and are generally in satisfactory condition.

The supply of labour continues deficient, and, in spite of the assistance of soldiers, women, and prisoners of war, there is difficulty in keeping the land clean, but the other work of the farm has generally been done without undue delay. The Whitsuntide hirings showed some further rises in wages.

The following local summaries give further details regarding agricultural labour in the different districts of England and Wales:

Northumberland, Durham, Cumberland, and Westmorland.—Although labour is scarce, particularly as regards skilled men, the situation does not appear to be serious in this respect, as the fine weather has allowed work to be kept well in hand. It is feared, however, that the thinning of the root crops will be difficult to arrange for. Wages were higher at the

Whitsuntide hirings.

Lancashire and Cheshire.—The supply of labour is deficient.

Yorkshire.—The supply of labour is deficient, the chief difficulty being as regards horsemen.

Shropshire and Stafford.—Skilled and casual labour are deficient, but with the help of soldiers, women and prisoners of war, work is well in hand.

Derby, Nottingham, Leicester, and Rutland.—Skilled labour is deficient. Wages still tend to increase.

Lincoln and Norfolk.—The supply of labour is deficient, and fields are becoming rather foul. Wages still tend to increase.

Suffolk, Cambridge, and Huntingdon.—The supply of labour is deficient, and hoeing of the crops is often being neglected in consequence.

Bedford, Northampton, and Warwick.—Skilled labour is short, but work appears to be well in hand, as good assistance has been rendered by soldiers, women and prisoners of war.

Buckingham, Oxford, and Berkshire.—Skilled labour is still deficient, but soldiers, women and prisoners of war are becoming more expert. Wages continue to rise in most places.

Worcester, Hereford, and Gloucester.—There is the usual deficiency of labour, but work is kept in hand by soldiers, women, and prisoners of war. Wages tend to increase.

Cornwall, Devon, and Somerset.—Skilled labour is everywhere deficient, and though great assistance has been rendered by women and soldiers the shortage is severely felt. Wages show a tendency to rise.

Dorset, Wiltshire, and Hampshire.—The supply of labour is generally short, but much assistance has been given by women, soldiers and German prisoners. Wages tend to increase.

Surrey, Kent, and Sussex.—The supply of labour is deficient.

Essex, Hertford, and Middlesex.—The supply of labour is deficient, but the assistance received from women and soldiers has saved the position from becoming serious.

North Wales.—The supply of labour, especially skilled, is very scarce in some districts; in others the supply appears to be about sufficient.

Mid Wales.—Labour is deficient, but good weather has made work easier so far.

South Wales.—The supply of labour is very deficient in most districts, and it is feared there will be a great difficulty in obtaining labour for hoeing and harvesting.

THE following statement shows that according to the information in the possession of the Board on 1st June, 1918, certain diseases of animals existed in the countries specified :—

Animal Diseases on the Continent. *Austria (on the 8th May)* Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Denmark (month of March).—Anthrax, Swine Erysipelas.

France (for the period 21st April—4th May).—Anthrax, Black-leg, Foot-and-Mouth Disease, Glanders, Rabies, Sheep-scab, Swine Fever.

Holland (month of April).—Anthrax, Foot-rot, Swine Erysipelas.

Hungary (on the 8th May).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Italy (for the period 29th April—5th May).—Anthrax, Black-leg, Foot-and-Mouth Disease (1,982 outbreaks), Glanders, Rabies, Sheep-scab, Swine Fever.

Norway (month of April).—Anthrax.

Spain (month of December, 1917).—Anthrax, Black-leg, Dourine, Glanders and Farcy, Pleuro-pneumonia, Rabies, Sheep-pox, Sheep-scab, Swine Erysipelas, Tuberculosis.

Sweden (month of April).—Anthrax, Black-leg.

Switzerland (for the period 6th—12th May).—Anthrax, Black-leg, Sheep-scab, Swine Fever.

No further returns have been received in respect of the following countries: Belgium, Bulgaria, Germany, Montenegro, Rumania, Russia, Serbia.

THE JOURNAL OF THE BOARD OF AGRICULTURE

Vol. XXV. No. 4.

JULY, 1918.

EDITORIAL NOTES.

AGRICULTURE has been the subject of a continuous series of Royal Commissions and Committees ever since the great depression set in at the close of the 'seventies of last century. The difficulty the supporters of agriculture always experienced on these occasions was to secure any general acceptance of their principle that a prosperous agriculture was so essential to the national life as to justify any departure from the economic theories then current concerning the relations of the State to industries. The pressure of the War has made food production a necessary element in national policy, and our own land must be made to do its maximum towards supporting its people. The farmer must be insured against the risk of the losses to which intensive cultivation is liable if the markets are dominated by foreign supplies. Not only must the farmer be insured, but the labourer must be guaranteed a living wage, and, as a necessary corollary, if the State is to assume a liability in order to render the holding of land a reasonably remunerative enterprise it must take powers to enforce a corresponding standard of production. The occupier of land must use it in the national interest. These are the principles embodied in the Corn Production Act, and are the basis of the operations of the Food Production Department and its delegates—the Agricultural Executive Committees.

The considered argument for the Corn Production Act may be read in the First Report of Lord Selborne's Sub-Committee of the Reconstruction Committee, though that Report did not appear until after legislative action had been taken. The changed relations between the State and Agriculture, however, do not end with the Corn Production Act, and many other reforms are necessary if the State is to be charged with

the duty of ensuring the greatest production from the land. The final part of the Report of Lord Selborne's Committee may be regarded as a survey of this further field. Its recommendations cover the whole ground of the reconstruction of our agricultural system as far as such reconstruction can be effected by legislation or departmental action. The questions are so various and so intricate, and many of them are still so dependent upon the conditions in which the country may find itself at the close of the War, that it is not to be expected that Lord Selborne's Committee could have completely explored all of them and arrived at conclusions which will be universally acceptable. Nevertheless a solution is put forward, together with the grounds upon which it is based, and for many years to come this Final Report of the Agricultural Policy Sub-Committee of the Reconstruction Committee must remain the text upon which discussion and action will be based. The Report therefore demands the closest study from all classes who are interested in agriculture and in increased food production.

The Report is too voluminous to be dealt with fully here, but the summary of the subjects it covers and the selected passages given at p. 385 afford some idea of its contents.

ONE of the most striking features of agricultural England to-day is the change in agricultural labour brought about by the War. Tens of thousands of farm workers have joined the Forces, horses are reduced in number, the labour of ploughing is increased and is being largely carried out by tractors, and a great amount of work is being done by women, soldiers, volunteer workers, school boys, and prisoners of war. The latest arrangement at the time of writing this note is that relating to War Agricultural Volunteers (see p. 467), and the hope may be expressed that a very large number of such men will be found to have enrolled.

THE Prime Minister's appeal to women (see p. 466) to join the ranks of farm workers to save the coming harvest will not fall on deaf ears, for it is quite certain that very much depends on women's labour in the harvest field, where the work done will rank with that of munition workers as of the utmost national importance. The excellent work done by women

on the land has formed the subject of many notes published from time to time in this *Journal*, including one or two notes in the present issue (see p. 455).

At a Meeting of the Incorporated National Association of British and Irish Millers, held at the Cannon Street Hotel on **National Institute** 27th June, the Rt. Hon. R. E. Prothero, **for Agricultural** M.P., President of the Board of Agriculture and Fisheries, referred to the need for producing suitable varieties of wheat and other cereals for growing in the United Kingdom. To this end it was desirable to establish a National Institute for Agricultural Botany on the commercial side, working in association with the Institute for Plant Breeding presided over by Professor R. H. Biffen. The object would be to ensure that as a useful variety of cereals was established, it could be handed over to the commercial side to be brought out on commercial lines through the seed agents. This would greatly accelerate the placing on the market of new varieties of cereals. The meeting was also addressed by Sir A. Daniel Hall, K.C.B., F.R.S., Secretary to the Board of Agriculture and Fisheries, by Professor R. H. Biffen, F.R.S., by Mr. Lawrence Weaver, C.B.E., and by Mr. A. E. Humphries, President of the Association. It was resolved that the Association should contribute £5,000 towards the endowment of the suggested institute of agricultural botany.

By an Order made last year by the Food Controller, sellers of agricultural seeds were at last required to declare the purity and germination of seeds offered for sale. **Seed Testing.** Such action had been advocated for many years, and may be regarded as a reform of considerable importance to food production. As was anticipated, very beneficial results have been secured. The Order of 1917 has now been replaced by the Testing of Seeds Order, 1918 (see p 477), which effects certain changes, the most important of which is that cereals are brought within the scope of the Order, whilst an innovation of considerable interest is that packets of vegetable seeds of certain weight must reach a prescribed standard of germination, failing which the fact must be declared at the time of purchase. Farmers should take advantage of the provisions of the Order, an account of which is given in Food Production Leaflet No. 47.*

* Copies of this leaflet can be obtained on application to the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1, together with a copy of Leaflet No. 297 (*Seed Testing*).

THE address by Mr. Guy to the Agricultural Club (printed at p. 402) will well repay the close study of farmers, for with **British Agriculture as a Business Proposition.** characteristic American energy it deals with several problems which require solving before British agriculture can be placed upon that sound basis of reconstruction to which we all look. It is hoped that other papers read before the Club will find a place in this *Journal*.

ATTENTION is directed to the article by Mr. Oldershaw on "War-Time Farming Problems," which deals with various problems which have come before the **War-Time Farming Problems.** War Agricultural Executive Committee for the County of Suffolk. This article should be useful to other County Executive Committees who may be faced with somewhat similar difficulties in the course of their work, and who may be interested to know how they have been met elsewhere.

IN recent issues (March, 1918, p. 1441, and June, 1918, p. 330) of this *Journal* notes have been published on the value of the **Weeds as Food.** rhizomes or creeping rootstocks of couch grass as a food for stock. In the present issue are reprinted notes from the *National Food Journal* on certain fodder substitutes (see p. 448), including heather, bracken, seaweed, and reeds, while bracken and heather were also the subject of a note on p. 233 of the May issue. The value of spurrey for forage was dealt with in this *Journal* in July, 1911, p. 292, March, 1912, p. 1020, and June, 1912, p. 212. Wherever this weed occurs in such profusion that it practically overruns the sown crop, as it occasionally does, depasturing the crop with sheep, which will also clear up the spurrey, may be very beneficial—more particularly on light soils, where this weed usually occurs. Animals have also been observed to browse upon Charlock (*Brassica Sinapistrum*, Boiss), Fat-hen or Pig-weed (*Chenopodium album*, L.) Redshank or Persicaria (*Polygonum Persicaria*, L.), and other weeds. Persicaria is stated to be a nutritious plant and has been given to horses and cattle as a green fodder. The Water Crowfoot (*Ranunculus aquatilis*, L.) is stated also to have been fed to horses and cattle, and been found very useful. Henslow remarks that cattle eat it with impunity, and that on the borders of the Avon cottagers used to support their cattle

almost entirely on it : " one man kept four cows and a horse so much upon it that they had not consumed more than half-a-ton of hay throughout the whole year."

THE Joint Committee of the Board and the Ministry of Food recently directed attention to the possible loss of farm produce by fire, and warned farmers to exercise great care as to the position of ricks. Hay will mostly have been saved before this issue of the *Journal* appears, but the corn harvest is upon us and the position of stacks will be under consideration. General convenience commonly leads to the larger proportion of corn crops finding a place in a rick-yard. This has one drawback ; in case of fire the whole group of stacks may be lost. It is more than ever important that the risk of such loss should be minimised, and the best plan is to stack the corn in different parts of the farm, as far apart as possible, at least 60 yards from a railway line, road or chimney, and near ponds if such exist.

AGRICULTURAL RECONSTRUCTION.

THE Agricultural Policy Sub-Committee of the Reconstruction Committee appointed by Mr. Asquith, then Prime Minister, in August, 1916, to consider and report upon the methods of effecting an increase in the home-grown food supplies, having regard to the need of such increase in the interests of national security, have just issued their Report (Cd. 9079, 1918). An Interim Report (Cd. 8506, 1917) was issued early in 1917, and was the subject of an article in the issue of this *Journal* for April, 1917.

The Committee was constituted as follows :—The Right Hon. The Earl of Selborne, K.G., G.C.M.G. (*Chairman*), Sir Charles Bathurst, K.B.E., M.P.,* Mr. C. M. Douglas, C.B., D.Sc., The Right Hon. Sir Ailwyn Fellowes, K.C.V.O., Mr. W. J. Fitzherbert-Brockholes, C.B.E., Sir Daniel Hall, K.C.B., F.R.S., Mr. W. A. Haviland, Mr. C. Bryner Jones, M.Sc., The Right Hon. R. E. Prothero, M.V.O., M.P.,* Mr. G. G. Rae, C.B.E., The Right Hon. G. H. Roberts, M.P.† The Hon. E. G. Strutt, and Sir Matthew Wallace, with Mr. H. L. French,

* Appointed in his capacity as a member of the Committee on Commercial and Industrial Policy.

† Resigned in February, 1917, owing to his Departmental duties making it impossible for him to attend the meetings of the Sub-Committee.

O.B.E., of the Board of Agriculture and Fisheries, and Mr. Alexander Goddard, the Secretary of the Surveyors' Institution, as Joint Secretaries.

The Most Rev. Dr. Kelly, Lord Bishop of Ross, and the Right Hon. Sir Horace C. Plunkett, K.C.V.O., F.R.S., were appointed by the Prime Minister in November, 1916, to represent Irish interests on the Sub-Committee.

The Report is a full exposition of the position of agriculture in this country. It opens with an historical preface in which is given a brief survey of the agricultural conditions during the last 100 years and the political and social factors exercising an influence on those conditions, and then proceeds to deal in detail with the various problems connected with British agriculture. A number of more or less drastic recommendations are made by the Committee with the object of ensuring agricultural reconstruction.

The subjects dealt with include :—

- (1) Effects of the agricultural depression ; (2) Need for a new agricultural policy ; (3) Agricultural wages ; (4) Price of wheat and oats ; (5) Effect of guaranteed prices on rents ; (6) Method of securing increased production ; (7) Sugar beet ; (8) Scope and limitation of the inquiry ; (9) The departments of agriculture ; (10) Organisation and co-operation ; (11) Agricultural credit ; (12) Small holdings, ownership, and tenancy ; (13) Village reconstruction, industries, and rural life ; (14) Tithe redemption ; (15) Local taxation ; (16) The Agricultural Holdings Act ; (17) Reclamation and drainage ; (18) Deer forests ; (19) The elimination of pests and weeds ; (20) The supply of artificial manures ; (21) Weights and measures ; and (22) Transport.

It is not proposed to give here a resumé of the whole of the Report, but it is thought that the following verbatim abstracts of some of the principal parts will give some idea of the Committee's views and recommendations, and speak for themselves :—

Introduction.—"2. We desire at the outset to explain that we were informed that the question asked us did not refer to war but post-war conditions, and our Report is drawn up from that point of view only. Nevertheless, it is evident that for some time after the War agriculture must be seriously affected by the conditions which have prevailed during the War. Any inducements and assistance, which the farmers receive now to keep their fields cultivated, or to cultivate additional land, will bear fruit in the post-war period, and may even be considered as direct steps towards the object we have in view. We trust, therefore, that we shall not be considered to have

passed beyond our legitimate subject when we express our conviction that farmers need and deserve all the help and encouragement which His Majesty's Government can possibly give them at the present time.

"3. The experience of the War has shown that the dependence of the United Kingdom on imported food has already involved the country in special difficulties, and in the future may become a source of real danger. We have found that it has increased the cost of the War; aggravated the difficult problem of regulating foreign exchange; and absorbed an undue proportion of the tonnage of the mercantile marine at a time when its services have been so sorely needed for other purposes. We are conscious also of the possibility of a development in the construction of submarines which in a future war might make impossible a continuous supply of food to the people of the United Kingdom from overseas. We hope and pray that the greater sanity of nations and their increased obedience to the Divine law may save our country from any repetition of the hideous catastrophe which has to-day overwhelmed Europe, but we can feel no positive assurance that this will be the case, and we do not think that we should be faithful to our trust for our descendants if we omitted to take any practicable measures to increase the national safety in a future time of need. We can well imagine that in some future struggle the comparative independence of the United Kingdom of a supply of food from overseas might be a determining factor of victory. Apart from these grave considerations, it is evident that, after the War, the financial and physical welfare of the country will demand that the productive capacity of the soil should be developed to the fullest extent. Burdened with a huge debt, the nation will be strongly interested in producing as much as possible of its food at home, in order that it may buy as little as possible abroad. Exhausted in man power, it will find in the expansion of the rural population of these islands the best restorative of its vitality and creative energy.

"4. We have approached the problem entrusted to us exclusively from the point of view of national security and welfare, and we have endeavoured to formulate a scheme of agricultural policy which may be generally accepted by the nation and adhered to through a long course of years."

Need for a New Agricultural Policy.—"16. We are confident that, as the years pass by and agriculture becomes more intensive in the United Kingdom, an increase of production will be reached which would now appear impossible to many

farmers, and that, if the agricultural policy which we recommend is carried out steadily and continuously, a great change will be effected within a generation.

" 17. Nothing in agriculture can be done by the wave of a magician's wand. Results can only be produced in the United Kingdom as in Germany by a constant and consistent policy. The State must adopt such a policy and formulate it publicly as the future basis of British agriculture, and explain to the nation that it is founded on the highest considerations of the common weal. It must be explained to landowners, farmers, and agricultural labourers alike that the experience of this War has shown that the methods and results of land management and of farming are matters involving the safety of the State, and are not of concern only to the interests of individuals. They must be plainly told that the security and welfare of the State demand that the agricultural land of the country must gradually be made to yield its maximum production both in foodstuffs and in timber.* The history of our country shows that, when once the path of duty is pointed out to them and they understand how grave is the responsibility put upon them, neither landowners, nor farmers, nor agricultural labourers will fail to rise to the emergency.

" 18. There is much excellent estate management and much high farming in the United Kingdom to-day, but there is also much slack estate management and bad farming, or management and farming which, while profitable to the persons interested, do not take national requirements as to food production into account. That this is so is known to all who have studied the present conditions of British agriculture. The causes of bad estate management and farming are lack of suitable education or of capital (often found in combination) on the part of landowners and farmers, the personal equation of character, the excessive encouragement of game, the acquisition of land for the sake only of its amenities, and the conviction that the State has no interest in the treatment of agricultural land and that it is the concern only of the individuals dependent upon it.

" 19. The general average of farming must be steadily and continuously raised throughout the United Kingdom ; the grass land and the arable land alike must be more intensively cultivated ; the improvement of live stock, for which landowners and farmers have done so much even through the years of acute

* The subject of Forestry was referred to another Sub-Committee of the Reconstruction Committee. (See this *Journal*, February, 1918, p. 1251.)

depression, must be progressive ; much grass land must be reconverted into arable ; the sugar beet industry and the manufacture of potato products can be introduced into British agriculture to its great advantage ; estates must be managed with a single eye to maximum production ; capital must be attracted to the industrial equipment and improvement of the land and to the operations of intensive farming ; agricultural labourers must be provided with an adequate supply of good cottages ; small holdings both of owners and of occupiers must be fostered to provide a ' ladder ' for the agricultural labourer and for the demobilised sailors and soldiers ; the organisation of agriculture must be developed ; the country must be permeated with a complete system of agricultural education ; the status of the department of agriculture must be improved and their powers enlarged and reinforced by association with existing agricultural and administrative bodies, both national and local. All these questions and others of much importance, such as Reclamation, the incidence of Local Taxation, Credit, the working of the Agricultural Holdings Act, etc., etc., will be dealt with in our Report, which will present a scheme of agricultural policy as one whole ; but we think it our duty to put in the forefront our conviction that a basis of security and stability of the conditions under which agriculture is to be carried on in the future must be the foundation of the whole structure, and that without it the increase of production, which we predict, cannot be realised.

" 20. We are of opinion that the conditions of agriculture must be made so stable that out of its profits the agricultural labourer can be assured a fair wage, the cultivator of the soil a fair return for his capital, energy, and brains, and the landowner a fair return for the capital invested in the land, and we believe that this stability can never exist so long as there is a possibility of a recurrence of the prices of the late period of depression.

" 21. We recommend that the State should fix a minimum wage for the ordinary agricultural labourer in each county, guarantee to the farmer a minimum price for wheat and oats, and take steps, as set forth in later paragraphs, to secure the increase of production which is the object of the guarantee. The cereal crops are the pivot of agriculture, and we do not consider that dairy and stock farming will in any way be prejudiced by our proposals. Moreover, as we have already stated, these very important branches of the agricultural industry can be more, not less, advantageously conducted on

arable land than on grass land. In the United Kingdom there is land so adapted to pasture that its retention in grass can be defended on economic grounds. There is also grass land the soil of which is a clay so sticky that in the climate of these islands under the plough 'season can only be got upon it' once in three or four years; and there is other land where the climatic conditions render the harvest precarious. It would be useless to plough such land. Of the remaining grass land a large proportion could be ploughed up with advantage to the farmer, the landowners, and the State. The interests of the State demand that more land should be put under the plough, and any landowner and dairy or stock farmer, who chooses to convert part of his grass land into arable, could at once obtain the benefit of the guarantee and at the same time increase the output of his particular products.

"22. We have no authority to consider the fiscal policy of the country as a whole; our reference, though a very important one, is strictly limited, and we shall confine our Report to an answer to it. At the same time we think it right to put on record our opinion that, if the State, for reasons of general policy, were to adopt a tariff on manufactured goods, then a tariff corresponding in degree (with the necessary differentiations between the products of the Empire, of allied, and of other countries) should be imposed on imported foodstuffs such as dairy produce, meat and corn, and that special consideration should be shown to the produce of the more intensive forms of agriculture (of which fruit and hops and flax may be cited as examples), where the capital invested, and the annual expenditure in cultivation, and the proportion of that expenditure on labour, are particularly large."

Method of Securing Increased Production.—"52. The Government has no fairy touch which will enable it to produce instantaneous results. It must work through, and by means of, the men who are now holding and cultivating the land. If it was so foolish as to try and do their work as well as its own, the only result would be to bring agricultural production to a standstill. There is no body of men in existence except the farmers of the United Kingdom and those who have qualified, or who are qualifying, to become farmers, who are capable of farming the land. Technical knowledge based on experience is just as essential for successful farming as education and brains and capital. It is when all these qualifications exist in combination that the best farming is found. Therefore the State must give time to all concerned to adjust themselves

to the new conditions dictated by considerations of national safety. It should formulate its policy and explain the reasons for it in simple definite terms ; it should make clear the part it proposes to play itself, that the policy explained will be steadily and consistently followed, and that, while the policy is being worked out, the agricultural industry will not be subjected to any harassing legislation. The State must, in short, take every means in its power to give confidence and a sense of stability to landowners, farmers and agricultural labourers. It must then tell those classes exactly what is expected of them, and appeal to their highest instincts of patriotism to put personal predilections aside, and to unite to carry out a policy on the success of which the safety of their country may some day depend. The standard set before their eyes should be the highest—not to be content till the whole soil of the United Kingdom is producing the greatest possible return of foodstuffs or of timber. It must be clearly understood that henceforth bad farming is a danger to the State, and that the waste of good land on game or games is inconsistent with patriotism. There will be plenty of room for game or golf in moderation, but too much game, or golf links carved out of fat land, make an inroad on the production of foodstuffs which can no longer be defended. Rabbits must be recognised to be what they are, a curse to both agriculture and forestry. There are localities where the rabbit defies extermination, but the effort to deal with the pest should never be intermitted. The theory in fact should be that rabbits are only to be tolerated in completely enclosed spaces, where the ground is of such a nature that it can more advantageously be devoted to the production of rabbits than of any other foodstuffs.

“ 53. When all this has been explained to them, landowners and farmers should be informed that they will be given reasonable opportunity to adjust themselves to the new conditions. The agricultural labourers being secured their share of profits by the institution of a minimum wage, the landowners and the farmers may be left to adjust their shares between them and also to come to an agreement (which is essential) about the relaxation of covenants against the ploughing of grass land or of any others which tend to discourage good farming. We are satisfied that they will have no difficulty in doing so much more satisfactorily than the State could for them.

“ 54. We entertain no doubt that landowners, farmers and agricultural labourers alike will realise the greatness of the

trust reposed in them, that they will rejoice at the recognition of the fundamental importance of agriculture to the national life, and that they will do all, and more than all, that their country demands of them. But we recognise that, when once the State has embarked on such a policy as we recommend, for the sake of the nation's safety, it can run no avoidable risk of its failure. Neither the idiosyncrasies, nor the incapacity, nor the lack of patriotism of individuals can be allowed to interpose even a partial barrier to the success of a national policy."

Board of Agriculture to have Power to take over Management of Estates.—" 56. We recommend that the Board of Agriculture* should be empowered temporarily to supersede the landowner in the management of the estate for all purposes essential to agriculture. It should put the estate, or such portion of the estate as it might deem necessary (except the mansion and the garden and park, if any, attached to the mansion), into the hands of a manager whose salary should be fixed by the Board of Agriculture and made a charge upon the estate. He should have the same powers in respect of the management of the agricultural land included in the estate as the owner had, and he should manage the estate as trustee for the owner. He should be a man of proved experience and capacity in the management of an agricultural estate, and he should render a yearly report and statement of accounts to the owner and to the Board of Agriculture. The balance of income, if any, derived from the estate after the payment of the necessary outgoings should be remitted half-yearly to the owner by the Board of Agriculture. When once the management of an estate had been so taken over by the Board of Agriculture, it should retain that management for five years, unless within that period there had been a successor in title to the original owner, in which case the estate should be handed back to his management at the end of the current farming year, if he so desires it and is prepared to accept such liabilities as may have been incurred in connection with it. If there had been no change of ownership within that period, the Board of Agriculture should be empowered to hand back the estate to the original owner at its termination if it was satisfied that the future management of the estate would be satisfactory. If it was not so satisfied, then it would continue to manage the estate for another quinquennial period, and so on from five years to five years, until there had been a change

* The Board of Agriculture and Fisheries for England and Wales ; and for Scotland the Board of Agriculture, Scotland.

of ownership. The owner should, throughout, be undisturbed in the exercise of sporting rights over the estate, subject to the power of the manager of the estate to prevent those sporting rights being exercised in a manner detrimental to agriculture or forestry. If the owner of such an estate is unable or unwilling to develop it for the purpose of agricultural production, the Board of Agriculture should have the power to borrow from the Land Commissioners and to develop it for that purpose by the expenditure of capital, the charges for which (interest and sinking fund) should have priority over all existing charges on the land charged according to the principle embodied in the Improvement of Land Act, 1864. During the period of supersession the power of the owner to make any fresh charges on the estate, or part of the estate, should be suspended, and the existing charges on it, whether by way of mortgage or of settlement, should be paid out of the proceeds of the land by the Board of Agriculture.

“ 57. For the guidance of all concerned it should be laid down that it shall be the duty of every landowner so to manage his estate, and that it shall be an implied condition in every lease or tenancy agreement, that the tenant of agricultural land shall cultivate the same according to the approved practice of the best agriculture, with a view to the economic production in the interests of the community of the greatest amount of food-stuffs (for man or beast), of which the land, having regard to its quality and position, is reasonably capable.

“ 58. Where land is being badly farmed by a tenant who holds a lease, and who persists in farming badly after being duly warned of the ultimate consequences, the landowner may bring the case before the Board of Agriculture, at the same time giving formal notice of the action to the tenant. The Board should thereupon ask the local panel to appoint assessors resident in another county than that in which the farm is situated to report upon the farm, and in due course should refer their report to the Review Committee. If, as the result of the unfavourable nature of the report in respect of the farming of the land, the Review Committee so recommended, then the Board of Agriculture should be empowered to call upon the landowner to give twelve months' notice to the tenant to quit, and that notice should have effect as if the tenant had held no lease, but was a tenant holding on a yearly agreement.

“ 59. In the later part of our Report we shall deal with agricultural organisation in all its aspects, but it is advisable to state here that in our opinion the Agricultural Department

in each county should, in carrying out the duties described in paragraphs 54 to 58 of this part, act in constant consultation with a National Agricultural Council or Board, which we hope may be formed so as to represent the progressive agricultural thought of the country and fulfilling analogous functions to those attributed to the German Agricultural Council by Mr. Middleton in 'The Recent Development of German Agriculture.' "

Rural Cottages.—"61. The provision of good cottages for agricultural labourers with ample gardens attached to them was an urgent question before the War. We desire to impress upon His Majesty's Government with the greatest emphasis at our command that there can be no hope of a satisfactory development of agriculture as long as the demand for cottages remains unsatisfied. The provision of these cottages should be taken in hand without a moment's avoidable delay after the War. In another part of our Report we shall deal with the improvement of the amenities of rural life, the reconstruction of stagnant villages, and the provision of an agricultural 'ladder' for the labourers by means of smallholdings. We mention these subjects now lest it should be supposed that we consider that the interest of the labourer in a national agricultural policy is limited to the questions of wages and housing. †

"62. Our attention has been directed to the point that some amendment in the Settled Land Acts may be desirable to allow a share of the proceeds of the sale of a portion of a settled estate, to be expended on improvements other than those specified in the existing Acts. . . . "

Need for Technical Advice.—"63. To bring about the changes in farming which we contemplate it will be necessary for the State, in addition to providing farmers with security against loss, to place at their disposal the best available scientific and practical advice. Indeed, it will be impossible to carry out the scheme (except with serious loss and wastage) unless it is accompanied by an important development of the facilities at present available in the United Kingdom for agricultural education, technical advice, and research. It will be necessary to insist on the importance of drainage, and to demonstrate throughout the country the best means of converting grass land to arable, the best methods of manuring, and the best varieties of seed; and to carry out on a much more complete system than has hitherto been attempted demonstrations devised to show that increased production can be secured without loss of profit. These subjects are, however, of such importance that we are deferring their consideration until the later part of our Report."

Organisation and Administration of the Departments of Agriculture.

—“ 106. The first thing necessary after the War will be to unite the whole Department under one roof. Proper administration is quite impossible when a Department is scattered into a dozen separate houses in half-a-dozen different streets. The Minister in charge of the Department should be styled, as now, President of the Board of Agriculture, but his salary and status should be raised to an equality with that of the President of the Board of Trade and the President of the Local Government Board. The staff must be increased and strengthened; especially it needs the infusion of a proper proportion of Class 1 of the Civil Service; those members of the staff, from whom expert, or at any rate practical, knowledge is required, should be selected by a combination of the systems of nomination and examination; the First Division men, who enter through the Civil Service examination should spend at least two out of the first five years of their service out of London; it is in our opinion important that they should get an early insight into the working of agricultural administration, either on the provincial staff of the Department or attached to the staff of local authorities. The provincial staff of the Department requires reorganising. Before the War the work of most of the provincial officers covered an impossibly large area, but many fresh appointments have since been made in connection with the campaign for food production; in some cases officers may be made responsible for all the work of the Board in a given geographical area; in other cases the work of officers must be specialised. In this paragraph of our Report we merely indicate the fact that the staff of the Department must be permanently expanded above its pre-war strength. In subsequent paragraphs we shall explain what the work is which in our opinion it should do. It may, however, be convenient in this place to draw attention to the fact that the work of other Departments of the State must affect the welfare of the rural population and the state of agriculture. This is particularly true of the Board of Education, and of the Local Government Board in respect of the housing problem. It seems to us necessary that in dealing with rural housing the Local Government Board, and in dealing with elementary and secondary education in agricultural districts, the Board of Education should work in close touch with the Board of Agriculture. The organisation of the Department in London must be remodelled in the light of experience and in consequence of its increased responsibilities. There is, however, one aspect of

this re-organisation to which we wish to draw special attention. It will certainly be necessary to create a Division charged with the management of all agricultural properties permanently or temporarily placed under the control of the Board of Agriculture. But the President of the Board, in his capacity of a Commissioner of Woods and Forests, is already responsible for the management of the agricultural properties of the Crown. We think that it would be a good plan to amalgamate the Agricultural side of the Office of Woods and Forests with the Management Division of the Board of Agriculture, and to put both sets of agricultural properties under the same control.

" 107. As in Scotland, so in England and Wales, the War Agricultural Committees of the County Councils* should be replaced by statutory committees, which, when constituted, should have powers of action independently of the County Councils, as in the case of the corresponding Committees in Ireland and of the Education Committees in England. They should be composed of men and women who are not members of the County Councils as well as of members of the County Councils, but in both cases alike it is essential to secure the services of persons with practical knowledge of agriculture or some other branch of rural economy, or representative of some special rural interest rather than of the different districts of the county. These Agricultural Committees should absorb the work of the existing Small Holdings and Allotments, Contagious Diseases of Animals, and Agricultural Education Committees (or Sub-Committees) of the County Councils, and of the Live Stock Committees established by the Board of Agriculture in various counties within the last few years (all of which Committees should be abolished), and they should undertake any other duties entrusted to them by Parliament or delegated to them by the Board. A County Council should have the power to set up more than one Agricultural Committee within its area, and the Agricultural Committee should have power to form District Sub-Committees.

" 108. The Agricultural Committees of England should elect two representatives from each County Council area to serve on the English National Agricultural Council, already

* Since this paragraph was drafted the Board of Agriculture has been empowered under Sec. 11 (2) of the Corn Production Act to authorize approved bodies to exercise any of the powers of the Board under Part IV. of that Act, with a proviso that the bodies so authorized shall, in the first instance, consist of persons who are acting as members of the County War Agricultural Executive Committees. This enactment, therefore, provides a natural link between the Statutory Committees we recommend and those already in existence.

suggested in paragraph 59 of Part I. of this Report.* The President of the Board of Agriculture should nominate to it persons representative of all agricultural interests, so that, however, the total number of nominated members shall not exceed one-third of the Council. The President and the Parliamentary Secretary of the Board of Agriculture should be ex-officio members. The Council so composed should meet at least twice a year to discuss questions of agricultural policy brought before it by the President, or by any of its members on due notice given, and the President or, in his absence, the Parliamentary Secretary should preside over its meetings.

“ 109. There is already in existence a Welsh Agricultural Council which is not statutory but does useful work. We recommend that this Council should continue to perform the functions of a National Agricultural Council for Wales, and that it should be made a statutory body for the purpose of advising the Board of Agriculture in regard to agricultural matters in Wales, to which the Board may delegate certain powers and functions relating to local administration. The Council should consist as at present of two members elected by each Agricultural Committee in Wales and Monmouth and the agricultural departments of the two Colleges, with not more than twelve members nominated by the President of the Board of Agriculture. The President and the Parliamentary Secretary of the Board of Agriculture should be ex-officio members, and the President or, in his absence, the Parliamentary Secretary should preside over its meetings. All the local work of the Board of Agriculture in Wales should be under the charge of a Principal Officer of the Board, who should be assisted by an adequate staff and have his headquarters and office at a centre in Wales convenient for North and South.

“ 110. We recommend also that there should be established an Agricultural Committee for England and Wales, composed of the President and Parliamentary Secretary of the Board of Agriculture, eight members elected by the English Agricultural Council, two members elected by the Welsh Agricultural Council, and three members appointed by the President of the Board of Agriculture. The Committee should meet regularly every quarter, and on special occasions when summoned. The President or, in his absence, the Parliamentary Secretary, should preside. It should deal with any business brought before it by the President, but its members should be free to

* See footnote on p. 396.

raise and discuss and pass resolutions on any subject of interest to agriculture or rural life in England or Wales. The proposed annual estimates should be laid before the Committee and discussed by it before being laid on the table of the House of Commons, and when so laid they should be accompanied by a memorandum expressing the opinion of the Committee upon them. All resolutions of the Committee should be laid upon the Table of both Houses of Parliament, if so directed by them.

"III. The National Agricultural Councils for Scotland, England, and Wales, and the Agricultural Committees for Scotland and for England and Wales, should be appointed afresh after every General Election of the County Councils; and the members selected, whether by the County Councils, or by the Presidents of the Boards of Agriculture, or by the National Councils, should hold office until the next General Election of the County Councils.

"112. If our recommendations are adopted there will be in existence in the United Kingdom four national Agricultural Councils, representing agriculture in Ireland, Scotland, England, and Wales. We suggest that it would be of great advantage to agriculture if delegates from these councils, say, thirty for England, and five for Wales, and ten each for Scotland and for Ireland, were to meet in conference once a year. The conference should never be held two years running in the same country, but in each country in turn, and the Minister responsible to Parliament for the agriculture of the country in which the conference is held should act as its President for the occasion. An officer of one of the departments of agriculture should be permanent Secretary of the Conference, and responsible for the custody of its records. We believe that the result of such conferences would be to diminish the chances of friction between the three Departments, to encourage the pursuit of a common policy, and to inform public opinion of the special difficulties and needs of agriculture and of its magnitude and importance as an industry. It would be a great encouragement to agriculture if His Majesty the King would graciously consent to become permanent Patron of the Conference of the combined Councils."

Education of Women.—"176. Before quitting the subject we have something special to say about the education of women who can play a great part in the reconstruction of agriculture after the War and whose intellectual interest in country life must be surely aroused if we wish to secure an increased rural

population. We hope that numbers of the women, who have been working on the land during the War, will wish to remain in agricultural occupations and to avail themselves of the openings which will be presented to them in many branches of farming such as dairying in its various forms, pig-breeding, and poultry keeping. We hope that every possible encouragement will be given to women so disposed and that the agricultural colleges will see to it that their courses are made suitable to them, and that the posts of lecturers are as open to fully qualified women as to men.

" 177. The subject has already been fully dealt with in the Report (1915) to the Board of Agriculture and Fisheries of the Agricultural Education Conference (Agricultural Education for Women)* presided over by Lord Barnard, which did such a great service in stimulating an interest in agricultural education. We desire to draw attention to this valuable document, to endorse its recommendations (*see* Appendix V.),† and to express our complete concurrence with the following reflection extracted from paragraph 2 of the Report: 'It is between 14 and 16 years of age that so many of the girls brought up in rural districts at present lose touch of country life. No matter what facilities for agricultural education may be offered to them later, these girls will have neither the taste nor the aptitude for it. This is a matter for serious consideration in view of the fact that it is women no less than men who are responsible for rural depopulation, and that there is no inducement in the form of higher wages which will tempt them to return.' The fact is that the local conditions which have brought about rural depopulation, bad housing, low wages, lack of prospects, affect women even more than men, and that the influence of women might be exerted in the opposite direction if they had been taught to make more comfortable homes with less drudgery, and if they had the necessary knowledge to enable them to build up a social order in which the natural advantages of country life could be made to counter-balance the artificial attractions of the town. Lord Barnard's Report deals with the problem of agricultural education as it affects all classes of women, but that of 'The Training and Employment of Educated Women in Horticulture and Agriculture' has also been treated by Mrs. Roland Wilkins in the *Journal of the Board of Agriculture* for October, 1915, and we recommend that article to the study of all those interested in the subject."

* See this *Journal*, December, 1915, p. 859.

† Not here printed.

Mr. Jesse Collings' Land Bill.—The Committee after discussing Mr. Jesse Collings' Land Bill offer the following observations :—

“ 241. After this review of the case we will conclude by recommending that the principle of the Purchase of Land Bill should be adopted and an Act passed to give effect to it. We attach special importance to Clause II of the Bill, which prohibits sub-division and sub-letting, and we strongly advise that the principle of this Clause should form an integral part of any purchase scheme.”

Village Reconstruction, Industries, and Social Life.—“ 243. The intimate connection between a plentiful supply of agricultural labour and an increase in the output of home-grown food—the primary object of our reference—was recognised in the early stages of our enquiry, and the recommendation with regard to farm wages contained in Part I. of our Report was framed to meet the competition of other and better paid industries. But, in our opinion, the question is not merely one of wages ; the conveniences and interests of town life exercise an attraction upon the young rural labourer which can only be met by offering counter attractions in the country districts ; and no agricultural policy will be worth having which does not aim at a better developed social life in our villages, at the introduction of fresh industries into the country districts, and at a large increase in the rural population. To this end an effort must be made to break through the stagnation in the life of too many villages by offering better opportunities for social intercourse and amusement, by arousing a stronger feeling of corporate existence and responsibility, and by opening out improved prospects of advancement to the energetic and hard working. With the advance of education a desire for greater opportunities has arisen among the more active and ambitious of the younger generation, causing them to covet the greater scope for their energies offered in urban districts. The proposals made under this head of our Report are designed to lessen the despondency of outlook sometimes associated with existing conditions, and to provide a machinery, which does not at present exist, for the improvement of village life.

“ 244. The difference between villages, even in the same neighbourhood, is often marked. Some seem to carry outward evidence of the prosperity and happiness of their inhabitants, while the aspect of others, less fortunate, seems to indicate with equal plainness a dull and colourless outlook. In the former are seen smiling gardens, well-cultivated and conveniently situated allotments, cottages in good repair, village playgrounds,

and social clubs and reading rooms ; in the latter, with land in abundance around, we find cottages possessing no gardens or insufficient gardens huddled together so as to reproduce some of the evils of town slums, and absence of all the amenities of life, and allotments so distant from the centre of the village as to be difficult of access and inconvenient for cultivation, the whole presenting an appearance indicative of the conditions prevailing therein. Enquiry will usually show that the difference is due to the fact that in one village a guiding spirit has exercised a sustained policy of development, based upon a clear perception of the requirements of the inhabitants and a study of the best means of providing for them, while the other has been without these advantages. In this connection it has been pointed out that an examination of the maps of the Ordnance Survey reveals how lacking in system has been the development of the ordinary village. In its midst, even adjoining the village street, may be often found land let with large farms, which might better be used for housing or other public purposes, for providing gardens, cow pastures or allotments, or for occupation with adjacent cottages. But it is no one's business to take the lead in demanding a better scheme of use for the land, nor does any machinery exist by which a rearrangement could be carried out. An atmosphere of stagnation prevails, and it is not surprising that the best men in such districts prefer to try their fortune in places offering greater scope for their ambition. The less efficient remain, and the deterioration in the rural working population, of which complaint is often made, becomes an accomplished fact.

" 245. Our plan for dealing with these important matters is set forth in detail in Appendix XI. It will be sufficient here to state the general nature of our recommendations.

" We are of opinion that the machinery of the Parish Council, the Agricultural Committee of the County, and the Board of Agriculture should be utilised for the purposes of village reconstruction, and that under proper conditions the necessary land should be acquired by compulsory powers if it cannot be acquired by voluntary agreement. If cottages are built or small holdings are created, we think that the inhabitants of the village should be given the option of tenancy or ownership, but that ownership should not carry with it the power of subdivision or of utilisation for a different purpose than that for which the house was built or the holding created. The money required for a scheme should be advanced out of public funds, and repaid by the Parish Council and the parties benefited,

following the exact analogy of a scheme under the Small Holdings and Allotment Act, 1908.

"246. We have been much impressed with the value of the work done by the Rural League in establishing village industries and of the Agricultural Organisation Society in establishing women's institutes, and we recommend that either the Agricultural Organisation Societies in the three countries or some analogous body should receive distinct grants for these specific purposes and that the task of fostering village industries and of forming women's institutes should be entrusted to them under the supervision and control of the respective Departments of Agriculture."

BRITISH AGRICULTURE AS A BUSINESS PROPOSITION.*

J. H. GUY.

FRANKLY, I am quite sorry that I consented to address a club of specialists on this subject, because I find that all I have learned of the industrial side of farming is of doubtful applicability in England. I am therefore compelled to dwell on your basic conditions as they affect the farming business, rather than on the particular phase with which I am familiar.

I was walking over a large estate with the owner a few weeks ago, and was told that some of the cottages cost £400, and were rented at 3s. per week. The rent was clearly uneconomic, but it was explained that a good man must have a good home, and a good home necessitated a good house, and it was a landlord's duty to supply the same, regardless of economics. Of course, the true meaning was obvious. The labourer received less than his earnings in cash, and the balance was paid in kind. But the results are far-reaching. In effect, the landlord keeps a grip on a part of his labourer's income, and insists on its application to house rent; floating capital, save the landlord's, is driven away from rural cottages; a bad landlord may withhold this portion of the labourer's earnings, and a good landlord can have the luxury of benevolence by giving his labourer no more than his just earnings.

These things may be good or bad, but they give a flavour to the business of farming in England something akin to the fourth dimension. Its existence is indicated, but one never feels quite sure of its reality. If it is real, it should be easy

* Address delivered to the Agricultural Club, 26th June, 1918.

to answer two simple questions—What is the business? and Who is running it? I am quite baffled in getting a definite answer to either question.

What is Farming?—Common sense would indicate that farming is the business of producing, for a profit, certain kinds of food, with such by-products as wool, and hides. But so direct and simple an answer by no means satisfies the many cooks who stir the agricultural broth.

To go no farther than the discussion in this club a few weeks ago, following Mr. Orwin's very interesting address in favour of large farms, there was first a lament because there has been a reduction in the number of agricultural workers which Mr. Orwin's plan would accentuate, and it was assumed as axiomatic that an increased number of workers was in itself a desirable thing. Quite the reverse would be assumed in any other industry. If England could mine her 250,000,000 tons of coal and iron with 500,000 people instead of 700,000 that would be considered a good performance as an economic proposition, as it would leave 200,000 available for additional production in other lines, and increase exportable surplus. Not so in farming. There are many who think that national well-being requires a numerous agricultural population, and this is specifically set forth by the Sub-Committee on Agricultural Policy as a prime objective. There was also introduced into the same discussion the broad social doctrine of the nationalisation of the land, not apparently because it was the best way to make farming pay, but as a sound doctrine in itself. There was also a demand for a highway to social advancement for the agricultural labourer, not observably in the interest of farmers or farming, but again as a social doctrine and an end in itself. And all these were apparently held to be relevant to the discussion of a plan to make farming profitable to the operator.

To an industrial manager like myself, it was like attending a meeting where every speaker used a different language, with Mr. Orwin my only compatriot.

Commerce and Agriculture Compared.—Compare this with a commercial undertaking. There we have a simple direct aim—the profit of the holder of ordinary shares. Every transaction is judged by that one standard. The purchase of materials and the employment of labour must be as cheap as possible. Interest on borrowed money must be low; sales price must be as high as possible; and finally no profits must be paid to anyone else if it can be avoided. To meet this last point the tendency is to reach back through all processes to the raw material, and

forward through all processes to the ultimate consumer. It is true that the word "cheap" must be interpreted in a spirit of enlightened self-interest. The lowest-priced labour is very rarely the cheapest, and the longest hours are not the most productive. But the objective is quite clear—to make profit for the ordinary shares—and it is the creed of many of us that the more intelligently this object is pursued the more easily can it be reconciled with the rising standards of social obligation.

In farming the fundamental objectives are much confused, and for the moment at least the British people seem inclined to conduct agriculture as an insurance against a submarine siege of these islands, as a nursery of manhood, and as a pension scheme for the returning soldier by giving him a strip of land for which he has fought. However desirable these things may be, they are not intrinsically business propositions, though they can be reconciled with business—at a price. If we grant the premise that farming is to be conducted for profit pure and simple, I would concur whole-heartedly in the application of the factory system to the farm, and would accept the conclusion as to farm labour that our choice lies between five labourers at £1 per week and two labourers properly equipped and directed at £3 per week—and rural depopulation be hanged. I shall, however, assume for the purpose of this discussion that any policy to command wide approval in this country, must effect a reconciliation between pure business and certain State requirements.

I find, unfortunately, that this is only the beginning of an answer to the simple question—What is farming? The precise place which is given to the several objectives determines the fundamental character of the industry. The most important of these is the degree to which safe food is to take precedence over cheap food. For several generations cheap food has been absolutely dominant, but under the stress of war there has been a complete reversal to safe food. When the alarms of war have subsided the safe food policy may become a very moderate programme, and it may again be necessary for the land to sell her fair face for the pleasure of the industrial magnate, because her honest housewifery cannot compete with that of younger countries. Arable may again diminish and pasture increase, and you may continue to depend on the incoming ships for daily food.

First Essential of an Agricultural Policy.—The first essential of an agricultural business policy must be for the industry itself

to frame a proposal to submit to the State defining in precise terms what it is prepared to do to meet national requirements, and the price. Consider for a moment the Corn Production Act. To an industrial manager, it would appear that the farmers are treated, and treat themselves, as helpless victims of blind economic forces, and it is the State which is taking the initiative in plans, and the burden of administration. And there is no real evidence that any other method is possible. To what organised body could the Government go for a guarantee that production would in fact be increased in an adequate degree for the money which it was prepared to spend? The result is a minimum price for corn which violates several important business principles, and involves a measure of Government control tolerable only during war.

Contrast this with the case of the Ministry of Munitions securing a forced and uneconomical output in the metal trades. By expert advice the Ministry ascertains a fair price which will produce a certain amount of output under ordinary trade conditions. Still greater quantities are required and the trade undertakes its production at a higher price for the increase, such higher price being based on the increased cost due to using semi-obsolete equipment. Further production is required and new plants are necessary which will be redundant after the War, and a price is fixed accurately measured by the higher depreciation on the war plant. A specific return is guaranteed for a specific payment, such payment being measured accurately by the degree of violation of economy, necessitated by the War demands. Where the industry is not organised, it has had to submit to Government control, with a loss to both sides due to divided interests and responsibility. If this one point could be brought home to the farming community, and they realised fully the annoyances of control, it should prove a very strong inducement to organise politically and industrially. The State, I am sure, would greatly prefer to deal with such an organisation rather than assume control. I have seen no evidence of the desire on the part of the much abused civil servant and so called bureaucrat to reach out into new fields except with great reluctance. On the other hand, the somewhat proud statement of the writers of the Agricultural Policy Report that the ownership of land is vested only in the landlords, and that in dealing with them the State knows exactly where it is and whom to hold responsible, is not altogether borne out by the situation revealed when definite action has to be taken.

There can be no satisfactory reorganisation plan which leaves the most important measures to be settled in the political arena. It is, therefore the first duty of the industry to present a reasonable proposition to the State, and to undertake to return a guaranteed minimum of production for a stated price. As to the price it is easy to state the basis. It must represent the ascertained offset to the unequal conditions of cheap land and virgin soil, as on the American continent, and sweated labour, as in Russia, less the cost of transport. It must not be a mere protection of inefficiency. This is vaguely recognised, but there is no sufficient assurance to the taxpayer that he is not being charged for incompetence, and it is bound to lead to a reopening of questions which would vitally affect any business policy.

Take a parallel with commerce. To increase sales, extra commissions and prizes are often given; but if sales were £1,000,000 per annum and the bonus offered were a flat 5 per cent. on all sales, no board of directors would face the risk of £50,000 dead loss before one extra sale was secured. If £100,000 increase of sales were secured an instant calculation would be made by every member of the board that the extra £100,000 of sales had cost £55,000 in additional sales expense. This course is, nevertheless, the one chosen by the Government, and this obvious criticism will be very generally made when peace returns. Some recognition must be made of the ability of certain lands to compete with little or no subsidy, and margin created for a high subsidy on less fertile lands. It is also essential that the Government assistance be asked for only so long as, and to the degree that, the unequal conditions exist.

Effective Management of the Agricultural Industry.—As to a guaranteed minimum production in return for the subsidy, there is at present no one to give and enforce the guarantee because there is no effective general management of the industry, and the obvious remedy is to create one. Unless the farming community is prepared to appoint a body from its own numbers, independent of the State, to make such a proposition, and to guarantee a valuable return to the State, there is only the alternative of State control to secure increased production.

Farming and Population.—There is also another unsettled point of primary importance in arriving at what farming is. That is the ideal, variously referred to as the reservoir or nursery of manhood, the back-to-the-land movement, or in its more prosaic form, a large home market for manufactures;

and finally, in its negative form, as rural depopulation. A reservoir of healthy and contented men and women is the phrase used by the Agricultural Policy Sub-Committee, and a more nebulous phrase on which to build a business policy one can hardly conceive. It leaves entirely in doubt whether we are to plan for large units, each equipped with a rounded organisation of accountant, purchasing agent, sales manager and the like ; or whether we are to plan for auxiliary common services for small units. On the basis of pure economics and open competition the larger unit must win, but if the creation of a large body of well-rounded business men is the ideal then again the industry must approach the State, name a price, justify its basis and guarantee a result. I am inclined to think that English sentiment tends towards the small unit with common services, and that any specific measures of business policy must be adapted to that end. But you will observe that the only answer I have been able to secure to my opening question "What is Farming?" has been one assumption on top of another.

Who is Running the Industry?—The other question—"Who is Running the Industry?"—brings equally indefinite results. The landlords apparently claim to do so ; but, when the matter is put to the test, the State has to take charge in default of any responsible body, and so we have the Food Production Department, the Agricultural Organisation Society, and other public or quasi-public bodies taking the place of an association of the industry.

It is reasonably evident to me that there are no definite answers to the two questions I have put, and that the fundamental character of the industry is still to be bandied about as an incident of fiscal and political controversies, with precedence to the noisiest.

Three Basic Conditions for Success.—The reorganisation of farming, like every other reorganisation, must absolutely settle three basic conditions to secure success :—

1. A management vested with authority commensurate with responsibility.
2. A dominant objective to give unity to the industry.
3. A policy of management which reconciles the parties at interest, and gives reasonable assurance of a profit to the operators.

All three are singularly lacking in the present conduct of English agriculture, and no provision has yet been made for their establishment. In the prosperous days of English farming all three were present. If I read English history

correctly, the management was a solid body of landlords with political power amply sufficient to discharge their responsibility to the interests they represented. The dominant objective was the profit of the landlords, who saw to it that the profit was sufficient to enable them to reconcile the parties at interest by meeting the social requirements of the time—to farmer, labourer and the State. It is by no means necessary that the same management, or the same main objective, should be restored to secure success. I can readily imagine several variations. But it is certain that the tide of prosperity will depend for its height and duration on the exact degree to which these conditions are met.

A Dominant Objective.—As to a dominant objective it is impossible within reasonable limits of time to examine the consequences of more than one, and I submit some considerations arising under a plan of management aiming at “a reasonable profit to the farmer.” All other aims I shall judge in the light of their effect on this single interest. I wish to make it clear that I express no opinion as to whether this is the right objective; I merely state that it is impossible to frame a sound business policy directed to several partially conflicting aims, and that I have selected one intelligent objective. Others which might be given first place, and which would require quite different policies and bodies of management, are:—(a) The profit of the owner of the land; (b) the home production of all food; and (c) the maximum agricultural population.

I venture to suggest to the Chairman that he should call on exponents of these policies to test the effect of giving them first place and see what offers they could make to other interests.

Definite Proposals.—I turn now to specific proposals to be incorporated in a business policy, which would first and always secure a reasonable profit to the farmer, and give due consideration to all other claimants for admission into reorganised business.

For this purpose we need in front of us a profit and loss account to guide us in examining the effect of the claims of the parties at interest, and I have constructed a rough statement of this character (Tables I., II. and III.).

The first criticism against farm management is on the part of the State. The State claims, with justice, that the output is an ill-balanced and sparse diet for over 35,000,000 people, about £3 10s. worth of food per capita per annum at farm prices, and part of that goes to city horses and for brewing. The balance required has naturally to be made up by imports,

of which it is estimated that perhaps £200,000,000 (1913 values) could have been raised on English farms.

I will not further labour the point that the first task is to form a body of farmers, with paid executives, for the purpose of preparing and supervising a plan to produce this additional food. The possibility of transforming the Food Production Department into a Farmers' Association at the close of the War is a Heaven-sent opportunity which should not be missed. The flexibility necessary to success can only be secured by the industry itself. I have seen this year chalk hills ploughed up at a great expense, when half the cost expended on more fertile fields within a mile would have produced in extra crops much more than the total yield of the chalk hills. And such examples could be multiplied indefinitely.

The price to be charged, and the general character of the organisation to secure this increased production, belong to the commercial side of the industry, and these I have discussed, but the methods of its production belong to the technical phase, and I shall therefore pass to the next business question—Who is to get the benefit of the increased production? For this I am compelled to present another table (II.). Here I have assumed that the output of 1907 is doubled, that is, an addition of £127,000,000, which I understand is well within the realm of possibilities. I have made arbitrary additions to the 1907 figures, keeping within the amount of imports, on each item.

In the distribution of the proceeds I have assumed that the farmers have organised and are entitled to any increased net return.

Labour remains at the same percentage, though, of course, double in amount. In actual practice, the percentage may be higher, due to forced production, and this will give one of the measures for arriving at a proper subsidy. The main point, however, is the rent. The farmers may well say we will continue to pay the same rent as at present, and will get our reward on the decreased percentage for this item.

We are told that there was a loss of £834,000,000 in the capital value of the lands of Great Britain between 1875 and 1904. Making a proportionate allowance for Scotland, this would leave approximately £700,000,000 in England and Wales, and would be comparable with the output in these two tables. Who can doubt that an income return on this £700,000,000 will be imposed on the agricultural reorganisation plan, if there is any chance to do so; it is in fact in progress of

imposition. At 5 per cent. on this capital the change would be 25 per cent. on the increase I have assumed. The threat of this imposition strikes at the foundation of any organisation of farmers as business men. It appears to me that there are two, and only two, ways of securing a businesslike solution. The first is for the landlords to operate the farms direct, and the other is for the farmers to buy out the landlords. Both solutions imply a scrapping of the elaborate paraphernalia of Land Courts, allowances to outgoing tenants, and erudite discussion about the three F's. The remedy is a Land Purchase Act giving the cultivator of the soil facilities and the right to purchase. The essential to business policy is that management and ownership shall run together. Imagine Swan & Edgar's at the corner of Piccadilly Circus exposing themselves to a revision of rent based on their earnings every seven years. No staple industry in the world except agriculture has been attempted on such a basis. It may be urged that landlords are considerate and neighbourly and do not take their pound of flesh. Such an intolerable position would have been ended long ago if they had. But in America we have decided that the potential ability to injure is almost as vicious as actual injury, and our anti-trust laws have been interpreted accordingly. It is intolerable to manhood that the upbuilding of years shall periodically be placed in another man's hands "to touch and remit after the use of kings." Ten thousand kings would upset any business. The English genius for compromise has made it work passably well at times, but it is my opinion that those times have passed. If farmers are to develop their scattered units into an organised industry, the threat of this undefined mortgage on their labours must be removed. If landlords are to organise the business, it is essential that they should reap their reward in the form of increased rental or return on capital, and their profit and loss account would then be as in Table III. It will be observed that in Table II. the farmer theoretically gets double the return that he would in Table III., and in practice this would, I think, be substantially true in time.

Future of Labour.—This matter is also of overwhelming importance to labour. The economic future of labour depends on the application of scientific management on the farm, standardised conditions, standardised operations, despatching, standards of performance, and an efficiency-reward.

An interesting pamphlet by Mr. T. B. Ponsonby is the only farm literature I have seen on the subject, but the matter has

received much study in commerce and we have learnt by our mistakes. Mr. Ponsonby barely mentions standardised conditions, but this is the root of the matter. If piece-work, bonus schemes, stints, differential rates, or any other form of efficiency-reward, is based on existing conditions, any improvement that involves capital or effort on the part of the farmer must be paid for by a reduction in bonus rate, though not in weekly total, and then the trouble begins. How can equipment be standardised under the English system of land tenure? I have seen farms where a very large part of all labour was obviously wasted by the bad arrangement of buildings and equipment, and a considerable expense would be necessary to cure it, but I doubt whether a new tenant who never made time-studies of each operation would pay 1*d.* extra in rent. My wife informs me that each meal prepared in our house in England takes $3\frac{1}{2}$ times the running about that it did in our American home, 300 ft. against 80 for afternoon tea for example, and she has properly scaled charts which have passed expert criticism, to prove her point. But there is no cure. Our temporary residence here would not justify pulling about scullery, pantry and kitchen, and the landlord would not find one person in ten who would pay for the rearrangement until after a period of occupancy. I examined last year time-studies in painting shell. In 25 establishments the labour hours per thousand shell varied as 5 to 1. The worst took five times as long as the best. The cure lay first in the arrangement of benches and machines, smoothing of floors and minor changes of that character, and second in instruction. There was little visible improvement in the physical equipment, but there was doubled efficiency shown in the reduction of cost and increased earnings to the workers. In the last year I have seen dozens of startling improvements of this character, most of which would have been stultified under a tenancy system.

The farm labourer lies under a burden of unintelligent and unnecessary chores (jobs), rendered inevitable by this extraordinary system of separating management from ownership.

Cost Accounting.—The farm labourer has much in common with the famous tramp who was willing to work for his breakfast, but went without rather than pile the firewood on the other side of the yard for no earthly benefit. Useless work strikes at the soul. Every hour of every day that is happening on most of the farms of England. And that leads naturally to the subject of cost account. It may comfort you to know that only 10 per cent. of American industry has any cost accounts.

Competent opinion added to my own unrivalled facilities for information on this matter leads me to believe that in England there is less than 5 per cent. In Germany it is 90 per cent. The paramount importance of cost accounts for the improvement of farming as a business, combined with the fact that it is one of few subjects not fogged by unsettled basic conditions, make the matter one of present practical interest. The trouble in the way of general application is the unfortunate fact that farm cost accounts present great technical difficulties. As a practical accountant, I do not believe that farmers will ever master the subject, and probably would not be justified in giving the time necessary to do so. Any accounts they are likely to keep would fail to reveal so many factors, that the accounts would mislead as often as they would correct his judgment.

My only hope lies in the recent development of machinery which renders possible centralised accounting from simple basis returns like time-cards, milk-weights and feed-tickets. This is not the time and place to discuss the technique, but I expect to see its use in England despite the difficulty of cumbersome weights and measures. The real trouble will be to induce farmers to make any returns, but that will probably be less difficult than to educate them in the intricacies of cost accounts. The choice is between a course that is psychologically difficult and one which seems to me intrinsically impossible.

Financial Side of Farming.—The commercial side of farming, that is the buying and selling of requirements and output, is of immediate practical importance, but here, again, a satisfactory solution is impossible, until we have a more definite answer to my question—"Who is running the business?" I will, however, present a few thoughts applicable to the problem whether the answer is landlord or farmer.

If we turn back to my first table, the output in 1907 is shown as 127 millions, and the value of the farms in England and Wales was apparently £700,000,000, and farmers' capital has been estimated at 40 per cent. that of the landlords. But placing the two together at £700,000,000 the relation of capital to gross output is over 500 per cent. The relation to net output, that is gross output less purchases, is nearly 800 per cent. against 115 per cent. as the average of English industry, exclusive of agriculture. In a typical trade connected with farming, that of the feed and fertiliser merchants, the merchants state that the relation is about 12½ per cent., which means

they turn over their capital eight times a year and the farm once in eight years. The high relation of capital to turnover is the first important fact on the financial side of farming. The second is that the farmer stands between the upper and nether millstones of commerce, in a peculiar degree. We all have the upper eternally rubbing us, but it does not grind because we can generally pass the price on to the customer. But the farmer has no distributing machinery and he cannot do this. I must again appeal to a table to illustrate the point (Table IV.)

That is, a purchase starts from the factory at 53 and gets on to the farm at 105, and a sale starts off the farm at 1s. 2 $\frac{3}{4}$ d., and gets to the consumer at 2s. 2 $\frac{3}{4}$ d. The farmer pays double costs and receives half the sales prices. Of course, there are legitimate expenses in between, but the facts contain a moral and constitute the second important point. The third I draw from another of my dull tables—the manufacturing activities of the Industrial Co-operative Movement (Table V.). From this it will be seen that over two-thirds of the total is composed of dressing the farmer's product. The summary of the three points is this :—

The farming industry requires to turn over its capital more frequently, to control its purchasing and distributing machinery so that it can pass on its fair and reasonable costs to the consumer, and to cease paying profits to every unwelcome inter-loper who can manage to intrude between the factory and the farm, and between the farm and the consumer. This can only be done by capital combined with expert management, and I am round to my starting point "where is the management?"

Lest it be said that I give only destructive criticism, I furnish a table (Table VI.) which contains the idea of a real business of farming. The figures can be filled in when my original simple questions are answered. The first column should contain the gross return from farming as paid by the consumer; the second, retailing costs only, no profits to middlemen; the third, the costs of bacon factories, slaughter-houses and wholesaling operations; the fourth, the cost of imported wheat and meat, by which I imply that the way to control foreign competition is to take a profit on its milling and slaughtering; and the last column is to contain the value of home farm products based on an intelligent understanding of costs.

If you will study the departments of Food Production and Food Control and the A. W. S., I am inclined to think there is a fighting chance for farmers to control their own business.

In conclusion, I commend to the attention of farmers that simple instrument, the funnel. The wide end should be at our pockets when we receive, the narrow end when we pay—not the reverse as at present.

APPENDIX.

Some of the figures in the tables below are very rough approximations, and are used in the text merely to show tendencies, as in the case of rent, which in Table I. is shown as £22,000,000 and 17·3 per cent. of the sales. In Table II. it is shown at the same figure in money, but is only 8·6 per cent. of the estimated increased sales. This is to indicate the manner in which the farmers would gain through increased volume, if the rent could be fixed.

† No conclusion is drawn in the text except from official figures.

TABLE II.—FARMER ORGANISING.

<i>Expenses.</i>		<i>Per cent.</i>		<i>Sales.</i>	
		<i>Millions. of Sales.</i>			<i>Millions.</i>
		£			£
Labour ..	60	23·5	Crops ..	105	
Feed and fertilizers ..	48	18·8	Animals ..	95	
Rent ..	22	8·6	Dairy produce ..	36	
Cattle for feeding ..	12	4·7	Fruit, etc. ..	5	
Implements ..	6	2·3	Poultry ..	12	
	148	57·9			
Farmer ..	107	42·1	Wool ..	2	
	£255	100		£255	

£251 per farmer.

£190 per farmer on assumption of 10 per cent. of sales for miscellaneous expenses and interest on capital.

Previous figures arbitrarily increased as to sales for an assumed increase—see text.

TABLE III.—LANDLORD'S ORGANISING.

	<i>Millions.</i>	<i>Per cent.</i>
	£	<i>of Sales.</i>
Labour ..	60	23·5
Feed and fertilizer ..	48	18·8
Cattle for feeding ..	12	4·7
Implements ..	6	2·3
*Farmer ..	43	16·7
	169	66·0
Landlord for return on capital and organization expenses ..	86	34·0
	255	100

* £100 per farmer.

Table with the same assumed increase as in Table II., arranged to show what landlords might expect if they organized the industry.

TABLE I.—ESTIMATED FARM PROFIT AND LOSS ACCOUNT (ENGLAND AND WALES): 1907 FIGURES.

Outgoings.			Receipts.		
	£	Per cent. of Sales.		£	Per cent. of Sales.
Labour	23.5	Farm crops sold off Farm	31.5
Feed and fertilisers	18.8	Animals	39.8

WAR-TIME FARMING PROBLEMS.

A. W. OLDERSHAW, M.B.E., B.Sc.,

Agricultural Organiser for East Suffolk.

Executive Officer to the East Suffolk War Agricultural Executive Committee.

IN view of the great importance of increased production in agriculture, and of the effort now general throughout the country to raise the standard of farming, a short outline of some of the problems arising in what is perhaps a fairly typical agricultural district should be of interest to readers of this *Journal*.

In East Suffolk the acreage of arable land, permanent grass and rough grazings in 1916 was as follows:—

Arable land	326,345 acres.
Permanent grass	129,176 „
Heath land used for grazing	12,924 „

Statistics of the acreage of woodland were not collected in 1916, but in 1913 the acreage of coppice, plantations and other woods was 18,543 acres.

The proportion of arable to grass land is very high. Quite a considerable proportion of the permanent grass consists of low-lying meadows, so that the proportion of upland grass is very small. The heath land consists of poor, light sand—in most cases too poor to be worth cultivating, but generally capable of growing forest trees.

Before the various problems met with are discussed it will be useful to describe briefly the soils of the county, in order that the reader may have some idea of the agricultural conditions prevailing.

Heavy Soils.—The heavy soils of East Suffolk are formed by the weathering of the geological formation known as “Chalky Boulder Clay,” which covers about 60 per cent. of the total area of the county. In the East Suffolk area all the soil on this formation can be ploughed with two good horses attached to a single-furrow plough, so that, although heavy, it is by no means so difficult to work as are some of the sticky clays of the Midlands, which require three or four horses to plough.

The soil is very retentive of water, and nearly always requires under-drainage before satisfactory results can be obtained from arable land. A large number of chalk stones are present in the Boulder Clay. This usually renders the application of lime to these soils unnecessary.

Nearly all the soils in this formation in East Suffolk are extremely responsive to basic slag, which forms an excellent means of improving poor grass land, and also gives good results on arable land, particularly for clover and beans.

The East Suffolk Boulder Clay works down to a heavy soil which is often poor, but when well farmed over a period of years is capable of yielding good crops of wheat, beans, and clover, and fair crops of barley and oats.

Light Soils.—In East Suffolk light soils occur chiefly on the geological formations known as "Glacial Sand and Gravel" and the "Norwich and Red Crag." The latter covers about 8 per cent. of the whole area of the county, whilst the former covers about 25 per cent., so that about one-third of the county is light land. The light soils vary in type from useful light loams to worthless blow-away sands. The better type of light loams, although often somewhat deficient in lime, give good yields of most farm crops. In the writer's opinion potatoes might be grown much more extensively than is the case on these soils, whilst sugar beet is also a most promising crop.

Mixed Soils are formed when the varying formations lie in proximity to one another. They are usually very useful from an agricultural point of view, and will grow almost any crop.

Alluvial Soils account for about 5 per cent. of the total area. They are almost all "marshes," *i.e.*, low-lying land on the banks of rivers or near the sea. They often make good grass land but are usually unsuited for tillage. Many of them might be much improved by an efficient system of drainage. In some cases, where the water is pumped up from the marshes artificially, the grazing lets annually at very high figures.

Having now shortly described the soils of the county we may proceed to investigate the special problems which the work of the War Agricultural Executive and District Committees has revealed.

Up to May, 1918, in the course of 15 months' work, the Executive Committee have dealt with problems arising on 468 farms.* This figure is entirely exclusive of the question of breaking up grass land, and of a large number of cases which have been dealt with by District Committees without reference to the Executive Committee.

Bad Farming.—Chief amongst the problems arising are those due to bad farming, *i.e.*, neglect to keep the land clean and to maintain its fertility. This may be due to the individuality of the occupier, to lack of labour or capital, or to a variety of other reasons. Bad farming was responsible for the trouble in about 75 per cent. of the cases which arose.

In most cases the occupiers were warned, while in many cases they were interviewed by the Executive Committee or by the District Committee, or by both. Good results have usually followed such action. Frequently occupiers were asked to act under the "supervision" of a good local farmer. In many

* This information and that which follows, relating to the work of the War Agricultural Committee, is rendered available by the courtesy of C. C. Smith, Esq., J.P., Walton Hall, Felixstowe, Chairman of the War Agricultural Executive Committee for East Suffolk.

cases this has proved a most successful arrangement, and the farmer in question has greatly improved his methods, to the benefit of both the country and himself. Although there have been exceptions, it has been found that as a general rule inferior farmers have been quite willing to take the tactfully-offered advice of a good local farmer.

In a limited number of cases it was found impossible to pursue the course described, and the tenancy of the occupier was terminated by the Board of Agriculture, at the request of the Executive Committee.

In other cases the course described was, for various reasons, impracticable, and the Executive Committee found it necessary to take possession of the farms and themselves farm them. In such cases it has usually been found possible to get good local farmers to manage the farms on behalf of the Committee.

Farms Managed by the County Agricultural Executive Committee.—

The total number of farms of which it has been found necessary to take possession in this way up to the present has been 16 (including a few small areas) the area involved being 1,977 acres. A short description of a few of these cases may be of interest to readers of this *Journal*, as showing the kind of problems which arose and the methods of dealing with them.*

A.—A farm of 150 acres of average, heavy land, had been allowed by the owner to seed itself down to natural grass within the past 5 years. The rough feed resulting consisted principally of water grass (*Agrostis*). Most of the farm had been arable until 3 or 4 years ago, but this was all unploughed when the Committee took possession. There was an enormous number of docks on the fields allowed to go down to grass recently, the docks having been allowed to seed freely for 2 or more years. An auction was held annually and the rough feed was let for grazing purposes. No one lived at the house, as the owner (who was also the occupier) lived at another farm. The Executive Committee took possession of this farm in the summer of 1917. A local farmer undertook to manage it on their behalf. The "rough feed" was steam cultivated and fallowed. The cropping for the harvest of 1918 will be 26 acres of wheat, 9 acres oats, 7 acres peas, 12 acres beans, 16 acres barley, 3 acres oats and tares. There are also 21 acres for roots and fallows. All the crops were dressed with suitable artificial manures. There was no farmyard manure available,

* The writer is indebted to Messrs. D. Black, J.P., and J. R. Grimsêy, O.B.E., J.P., for particulars regarding two of these farms. The gentlemen mentioned are acting as honorary managers of the farms referred to, on behalf of the Committee.

no stock having been kept owing to the absence of food for them. At the time of writing (May 1918) all the crops look well.

B.—Another farm of about 350 acres of useful heavy land came under observation. It was owned and occupied by a gentleman who had a business in an adjacent town and who did not properly understand farming. He had in past years erected unnecessarily elaborate farm buildings, with the result that the farm had cost him much more than it was worth. Since 1915, finding himself very short of labour he left part of the farm severely alone, the stubbles being unploughed. The Committee took possession in June, 1917, and steam cultivated and fallowed a large area of the neglected land. In the autumn, the owner decided to let the land, and having found a tenant who met with the approval of the Committee, he did so, the Committee retiring from possession. It is worthy of note that in providing labour for this farm the Committee were greatly helped by the policemen-ploughmen sent out by the Food Production Department.

C.—In another case a farm of about 500 acres, partly light and partly a heavy loam, had been farmed "off hand," *i.e.*, by a farmer who lived elsewhere. It had been let at a low rent, and the premises had been allowed to get into a very bad condition, both owner and occupier having adopted the principle of "spend as little as possible." The farm is naturally quite useful land, but was in a very poor state. The tenant gave up possession at Michaelmas, 1917, and the landlord was apparently unable to let it owing to its generally neglected state, the house, a very fine one, being uninhabitable. The owner took no steps whatever to cultivate the farm. The Committee took possession, and with the aid of motor tractors and soldier labour have succeeded in getting it into cultivation.

There have been sown for the 1918 harvest 77 acres of oats, 21 acres of peas, 30 acres rye, 64 acres barley, 3 acres vetches, 30 acres lupins, and 30 acres of roots. Seventy acres, which are in a very foul condition, including one field which has been untouched for several years, are being fallowed. The Committee did not enter into possession early enough to get any wheat sown.

All the above crops have been dressed with suitable mixtures of artificial manures. At the suggestion of the writer a strip in most of the fields was left undressed. These strips afford ocular demonstrations of the value of suitable artificials on such farmed-out land.

If the Committee had not taken possession of the farm it is probable that no corn whatever would have been grown for the 1918 harvest.

D.—Another farm of good, heavy land, about 150 acres, was taken possession of by the Committee. It had been farmed by the owner, who lived some distance away. To illustrate the state of the farm it may be mentioned that the Committee found it necessary to burn the second year "clover" crop, as it consisted chiefly of weeds, the seed of which would have germinated if the crop had not been burnt. The Committee entered into possession in the summer of 1917, and have now 48 acres of wheat, 17 acres barley, 4 acres oats, 7 acres peas and 6 acres beans on the farm. The wheat when inspected late in May looked so well that there was a fear that it might lodge before harvest.

PROBLEMS DUE TO NATURAL CONDITIONS OF THE LAND.—We may now consider the various problems which arise owing to natural conditions of the land, such as wetness or poverty.

Drainage.—The problems associated with drainage may be divided into two classes: (a) those connected with main watercourses; (b) those connected with the actual drainage of individual fields, either by pipe-drains or otherwise. The latter class is generally only concerned with the heavier types of land. It was found that in East Suffolk the main watercourses were in a very neglected state. The course of the water in most streams was more or less impeded by the growth of bushes, trees, etc. Owing to lack of a central authority dealing with the whole stream in question concerted action in the past has been impossible. A man will not cleanse his portion of a stream unless his neighbours further down will do theirs. The result of this is that land near the stream is flooded, and the outfalls of drains and ditches are blocked up owing to water being held back. In view of the great scarcity of labour it is impossible at the present time to deal with all the streams in the county. With the help of German prisoners, however, and in conjunction with the Norfolk War Agricultural Committee, a commencement has been made in cleansing the River Waveney, which acts as a boundary between the two counties.

In the 10 years before the War, a good deal of pipe-draining was done in East Suffolk, and a little has been done since the outbreak of War, but the cost of the operation has become so high as to cause hesitation on the part of farmers before undertaking the work, even if labour has been available. Mole-

draining gives very good results on many heavy soils in East Suffolk, and has been and is being extensively carried out. In general it may be said that unless under-drained in some way or another, East Suffolk heavy soils give very inferior results. When well drained, generously manured, and kept clean, most of them may be relied upon to produce very useful crops of corn and roots.

Poverty of the Heavy Land.—Probably half the Boulder Clay area in East Suffolk may be accurately described as poor, heavy soil, the remainder being good corn-growing land of a heavy type.

A considerable area of the poorer heavy land was allowed to go down to grass during the period of agricultural depression. In many cases no grass seeds were sown, but the land was allowed to seed itself down naturally. One of the first grasses to appear in land of this type when left to nature is "Water Grass" (*Agrostis*), and to-day many thousands of acres of land are in "grass" which consists largely or partly of *Agrostis*. As a general rule better grasses and white clover gradually make their appearance after some years. When neglected for a number of years, being merely "rough grazed," thorn bushes often appear, and from information available it appears that in the spring of 1918 there were no fewer than 1,500 acres of heavy land covered with thorns or brambles, most of the poor, heavy-land parishes contributing to this total. Sometimes quite useful heavy land will grow bushes and brambles in this way if neglected over a period of years.

It is suggested that if the poor, heavy land referred to had been frequently slagged, the bushes removed as they appeared, and the ditches kept cleaned out, this trouble would not have arisen in its present acute form. It is almost certain that the expenditure involved in these operations would have been very profitable to the owners and occupiers.

Use of Basic Slag.—A small area of grass land of this type, taken in hand by the East Suffolk County Education Committee in 1901 and slagged 3 times in a period of 10 years, gave an average yield of 28 cwt. of hay per acre per annum, whilst an adjoining piece receiving no manure gave an average of 9 cwt. At current prices this resulted in a total profit to the occupier of £23 12s. 6d. per acre over the period.

The experimental field is very similar in character to a large area in East Suffolk, and there can be no doubt that had the whole of such land in the county been slagged 3 times during the 10 years preceding the War, its productive capacity would

have been enormously increased. It would also have accumulated a considerable store of fertility from the air by means of the nodules on the roots of the white clover, the growth of which is encouraged in such a remarkable manner by the application of slag. If slag had been applied to all this land there can be no doubt that much of it would have been more worth ploughing up at the present time. As matters are, it is unfortunately true that where slag has not been applied, much of this land is really too poor to plough up with a reasonable prospect of a crop, so that the limited amount of labour available is better spent on land which will give a better return.

If all the basic slag produced in Great Britain before the War had been used at home, large areas of our poor heavy-land pastures would be in a much better condition than they are to-day, and our national food supplies would have been correspondingly more secure.

Very large quantities of slag have been used, however. The writer was not concerned in any way with the establishment of the Experimental Station at Saxmundham, as he did not come to the county till 1911, so that he can fittingly pay a tribute to the great good done to agricultural production in the district by those who were instrumental in establishing that station. Not the least of the benefits conferred upon local agriculture has been the demonstration of the value of basic slag upon Suffolk poor heavy clay soils. It is probable that Saxmundham reflects the requirements of most poor clays in the Eastern Counties.*

Ensilage.—If, in the future, the food requirements of the nation necessitate the breaking up of large areas of these poor, thin-skinned heavy soils, great skill will be required if adequate returns are to be obtained from them. There can be no doubt, however, that even the poorer clays, in many cases now growing only rubbishy grass, could be made much more productive if well drained, manured and farmed. The writer still holds the opinion expressed elsewhere,† that the introduction of ensilage would increase the productivity of this class of poor clay soil. Oats and tares usually grow well on it, as does lucerne also. These crops make excellent silage and produce a much greater weight of green fodder per acre than the poor grass of which we see so much. Lucerne seems especially

* See Guide to the Experiments at Bramford and Saxmundham, 1906, T. H. Middleton, M.A.

† "Modern Ensilage Practice," A. W. Oldershaw: *Transactions of the Highland and Agricultural Society of Scotland*, 1917.

suitable as a means of keeping such soils in cultivation. There is little expense on it, it is very productive, and when ploughed up two or three good crops are almost sure to follow owing to the nitrogen it has accumulated from the air—provided one is fortunate enough to escape the depredations of the wireworm. Oats and tares also are a most productive crop even on poor, heavy land. It has been found that 14 tons of green oats and tares can easily be grown on good land* and on poor, heavy soil at Saxmundham, 11 tons 15 cwt. per acre of green tares alone have been weighed. On the same soil the average weight of a "no-manure" plot on old pasture for four years ending 1917 was only 1 ton 16½ cwt. of green grass per acre, whilst a similar plot manured with 10 cwt. of high-quality slag per acre yielded 3 tons 15½ cwt. green grass per acre.† This latter figure, although showing a great increase as a result of the application of the slag, compares very unfavourably with the tares in respect of green matter per acre.

The general question of poverty of the soil has also arisen in an acute form on large areas of heavy land still under the plough. This land has been arable for a long time and is thoroughly farmed out. There appears to be no cheaper way of enriching it than growing lucerne. Unfortunately, however, the growing of that crop, like the application of basic slag to poor grass land, takes years before its full effect is seen upon the soil. Yet the fact remains that most, if not all, Suffolk heavy clays will grow lucerne well if thoroughly drained. The growing of lucerne, like the application of slag, is an economic proposition—it will "pay" the man who does it, and probably "pay" him well. At the county experiment station at Saxmundham, on a poor Boulder Clay, an average weight of 3 tons 8 cwt. of lucerne hay per acre was obtained over a period of 6 years (1903–1908) from a plot which received an annual dressing of 2 cwt. of superphosphate and 1 cwt. of muriate of potash per acre. An adjacent plot receiving no manure gave an average yield of 25 cwt. of lucerne hay per acre. In a field near to this, some further plots were started in 1911 and mown every year for 5 years. Here the "no-manure" plot gave an average of 2 tons 13 cwt. of lucerne hay per acre per annum, whilst a plot receiving 2 cwt. of superphosphate annually gave 3 tons of lucerne hay per acre per annum. In the field in which the first experiment was

* This *Journal*, July, 1906: "Cost of Production of Silage," A. Amos, and A. W. Oldershaw.

† This *Journal*, November, 1917: "Yields of Grass from various Basic Slags," A. W. Oldershaw.

conducted are some grass plots which have been manured in various ways. One of these received a dressing of 7 cwt. of superphosphate and $3\frac{1}{2}$ cwt. of kainit in 1901, 1904, 1907 and 1912. The average weight of hay on this plot for 11 years was 27 cwt. per acre. A "no-manure" plot gave an average yield of $9\frac{1}{2}$ cwt. per acre. From these figures it appears probable that as a general rule, on this type of soil and with similar manurial treatment, lucerne will give more than twice as much fodder per acre as will grass. It is probably also more independent of manure.

It is evident that the general problem of the poverty of the soil is a very formidable one. On heavy land it seems useless to attempt to solve it until the land is efficiently drained. Once that is done much may be hoped for by the growth of nitrogen-accumulating plants such as lucerne and tares, in addition to those commonly grown, such as beans, peas and clover. By encouraging the growth of all leguminous plants, and so enriching the soil in both nitrogen and phosphates, basic slag and superphosphate are of the utmost value on such soils. Both manures may be used on either arable or grass land, and may be expected to repay their cost many times over.

The introduction of ensilage seems very promising. By producing a larger bulk of green stuff at home and so making the manure heaps bigger, more of the farmyard manure which these heavy soils so badly need will be rendered available, and the stock-carrying capacity of the farms will be increased. In this connection reference may be made to the scheme of the Food Production Department,* whereby assistance is given to farmers and landowners in the erection of concrete or brick silos.

The process of the improvement of poor, heavy land is a slow one, but it is also sure, and there can be very little doubt that fair returns can be hoped for if generous manuring is associated with skilful husbandry.

Poverty of the Light Land.—As has been previously noted, about one-third of the total area of the county consists of light land. Probably about half of this is useful soil capable of growing good crops if generously manured.

Use of Phosphates.—Some of this light land is exceptional in containing ample supplies of available phosphates. Thus, at the experimental station at Bramford, near Ipswich, conducted by the East Suffolk Education Committee for some years, it was found that soluble phosphates in superphosphate gave practically no results and in some cases did actual harm. This

* See this *Journal*, May, 1918, p. 149.

failure of superphosphate has been shown by Professor T. B. Wood* to be due to an exceptionally high percentage of available phosphate in the soil at Bramford.

In his report on Experiments at Bramford, 1906, Mr. (now Sir) T. H. Middleton† points out that as superphosphate is an acid manure it is quite possible that its use year after year on such soil may be injurious. The experience of farmers on other light soils near Ipswich indicates that superphosphate occasionally gives disappointing results. It is worthy of note that coprolites or phosphatic nodules occur in deposits in these districts, but whether the presence of these deposits is in any way associated with the high percentage of phosphates in certain soils is not known to the writer.

The extent to which neutral or basic phosphatic manures, such as steamed bone flour and basic superphosphate, are likely to give results on light soils having an average phosphate content is uncertain. The writer has evidence which leads him to think that on some of the light soils in this county the inclusion of neutral or basic phosphates in the manure for such a crop as potatoes is desirable.

Thus in an experiment with potatoes on a light soil near Hoxne in 1915, 1 cwt. of sulphate of ammonia, 4 cwt. of superphosphate and 1 cwt. of muriate of potash gave 10 tons 12 cwt. of potatoes per acre, whilst the substitution in this manure of basic superphosphate for the acid superphosphate gave 11 tons 2 cwt. of potatoes—an increased yield of 10 cwt. per acre.

The question, however, is one which requires further careful investigation, but from knowledge available up to the present, the light land farmer in Suffolk may more safely use a neutral or basic, rather than an acid phosphate.

Potash and nitrate of soda gave remarkably good results at Bramford Experimental Station when applied to suitable crops. Thus, 1 cwt. of muriate of potash applied annually to lucerne increased the average annual yield of lucerne hay over a period of 6 years (12 cuttings) from 45 cwt. to 61 cwt. per acre.

Most of the better light soil of East Suffolk is probably well suited for potatoes, although that crop has not been very much grown in the past. Sugar beet also promises to be a most useful crop.

* See paper by Professor T. B. Wood in the *Transactions of the Chemical Society*, 1896, p. 287.

† Guide to the Experiments carried out at Bramford and Saxmundham by the East Suffolk Education Committee in 1906, by T. H. Middleton, M.A.

Probably one-sixth of the total area of the county may be described as poor, light soil, and of this a considerable area is only just on the margin of cultivation or is actually derelict. These poor, light soils are not suited for corn growing, with the exception of rye and lupins. In dry seasons, which occur very frequently, the barley may fail to come out into ear, and so produce nothing. The soils are more suited for growing green crops for sheep, and on the better soils for growing potatoes and sugar beet.

Folding Sheep.—Large flocks of sheep are kept by many of the light land farmers, and are folded on the arable land. There can be no doubt that this is one of the best ways of managing this class of land. The manure is produced on the land where it is wanted, it is ploughed in with very little loss, and the land benefits by the treading of the sheep. Advantage is taken of the nitrogen-accumulating powers of leguminous plants to enrich the soil, and large quantities of both mutton and wool are produced. It is important to remember, however, that the folding of sheep only enriches the land in phosphates and potash when considerable quantities of artificial foods are fed. The quantity of lime added to the soil even when these foods are fed, is small. The light land farmer, by taking every opportunity of adding potash and lime as such to his soil, when he has reason to believe it is poor in those ingredients, will in all probability much increase its productivity. Heavy folding, even with plentiful cake and corn, does not make up for poverty of the soil in lime, but it undoubtedly adds considerably to the stores of the other essential plant foods. Folding without artificial foods or manures does not enrich the soil in phosphates and potash, but only in vegetable matter and nitrogen.

Fruit Growing.—Fruit growing has undoubtedly many possibilities, even on poor, light soils. At Hollesley Bay Labour Colony a large area of light soil has been planted with fruit, quite a considerable stretch of derelict heath land having been utilised for this purpose. The results obtained have been wonderfully good, and the colony has now hundreds of acres under fruit, and that grown by them is amongst the finest produced in England or in any other country.

Sandy Heath Land.—A large strip of sandy heath land, stretching nearly the whole length of the county, a few miles from the sea, consists of poor, light soil probably better suited for forestry than for agriculture. At present it produces practically nothing.

Lupins.—In various parts of the county there also exist areas of poor light land, which are only just on the margin of cultivation. On such land lupins are a very useful crop, although in a dry season even they fail. If, however, a good crop of lupins can be ploughed in, a fair crop of rye may often be obtained as a following crop.

Chalking.—Much of the poor light soil of East Suffolk is very deficient in lime, and remarkably good results have followed the application of chalk. There are extensive chalk pits at Bramford and Claydon, near Ipswich. The usual custom in the past has been to apply from 12 to 40 tons of chalk per acre. At present the cost of obtaining and transporting the chalk where required is almost prohibitive, even if the labour could be obtained. Unfortunately also, many of the districts where it is most required are some distance from a railway.

It is worthy of note that a large owner of light land in East Suffolk has become so thoroughly convinced of the value of chalk on his estate that he has purchased a field about 10 miles away, in which the chalk is close to the surface. After the War he proposes to open a quarry there to deliver the chalk by means of a motor lorry to various portions of his estate, direct to the farms where it is required.

The question of the smallest quantity of chalk or lime per acre which can be applied with satisfactory results is one which requires further investigation. Dr. Russell* estimates the annual loss at about a load and a half per acre per annum. He also states that in the counties round London in the old days the dressings were 80 to 100 loads per acre, but that nowadays dressings are smaller—about 50 to 60 loads per acre. Of late, considerable quantities of ground Buxton limestone, applied at the rate of 1 to 2 tons per acre, have been used in Suffolk, and possibly if the local chalk could be similarly ground, and applied by means of a manure distributor, results might be obtained which, although only temporary, might be sufficiently good to induce the tenant farmer to practice this method, owing to the comparatively small initial expense involved.

From an inquiry conducted by Mr. W. A. Cox of the Food Production Department, and the writer, it appears, that ground chalk could not be placed on the market in East Suffolk at the present time at much less than 20s. per ton, bags

* "Chalking: A Useful Improvement for Clays overlying the Chalk,"
E. J. Russell, D.Sc. This *Journal*, October, 1916.

extra (returnable). Lump quicklime could be produced from the chalk at about 30s. per ton. Since dry chalk only contains about half its weight of quicklime, it is evident that lump quicklime at 30s. per ton is much cheaper than ground chalk at 20s. The quicklime could be reduced to a fine powder by slaking, and sown with a manure distributor or spread from small heaps, as described in Leaflet No. 170 of the Board of Agriculture.

In East Suffolk, "crag" obtained from local pits has, in the past, been largely and successfully used as a source of lime. It consists chiefly of broken shells, and was applied at the rate of 20 loads and upwards per acre.

The effect of chalk is most evident upon certain crops, particularly on clover and lucerne. The writer examined a field on the farm of Mr. Wm. Paul, at Hemley, recently. Part of this field had been chalked 10 years previously and part had not. The difference between the two portions was remarkable. The crop was clover, and on the portion chalked there was a good plant, whilst the part unchalked consisted largely of sorrel. By the courtesy of Mr. Reynolds, Mr. Paul's steward, the weight per acre of the two portions was ascertained. On the unchalked part the yield was 14 cwt. of hay per acre, consisting largely of sorrel, whilst on the chalked part 26½ cwt. per acre were obtained, consisting almost entirely of clover. A difference of this kind in the course of years is certain to exert a profound influence on the fertility of the soil, owing to the larger quantities of vegetable matter and nitrogen stored up in the soil by the heavier crops of clover.

Dr. Russell very kindly investigated a case in the Parish of Leiston which is in many ways typical of the poor, light soil of the district. On the soil in question it was found that lucerne grew in patches; in some places it grew quite well, whilst in others it would hardly grow at all.

Dr. Russell* kindly analysed the soil on these patches and ascertained that the amount of carbonate of lime on the patches where the lucerne grew well was 0.8 per cent., while that on the patches where the lucerne would not grow was only 0.07 per cent. It is evident, therefore, that on soils of this type the application of lime or chalk is almost essential to success. Once one can get lucerne or sainfoin to grow the problem of the improvement of these soils is almost solved, as these crops enrich them so much that the succeeding crops are almost certain to be fairly good.

* E. J. Russell, O.B.E., D.Sc., F.R.S.: "Manuring for Higher Crop Production," p. 3.

Typical Poor, Light Soils.—On the poorer light soils of the county, almost every plant food appears to be present in very small quantity, although, as previously noted, certain (though not all) Suffolk light soils contain phosphates in abundance. The typical poor, light soil is undoubtedly very poor in vegetable matter, in lime, and in nitrogen, potash, and phosphates. In a district with a rainfall as low as that of Suffolk this poverty in vegetable matter is fatal to the successful production of crops. The crops fail at a critical period owing to drought, when the presence of ample supplies of vegetable matter would possibly hold the moisture and enable them to survive.

Ordinary grass, on such soils and with an average season, produces very little and in some seasons almost nothing. Very fair results have, however, been obtained on some farms from modified Elliot's mixtures, containing the various plants suggested by Elliot as deep-rooting and drought-resisting, and in addition a few pounds per acre of lucerne. In such mixtures kidney vetch usually succeeds fairly well. It is doubtful, however, if such mixtures possess any advantage over lucerne, although they are useful for a change.

If ample supplies of farmyard manure were employed no doubt these soils could be much improved, but unfortunately they are not available. The productivity of the soil is at a very low level, and consequently very small yields of straw or green stuff are secured, and very little farmyard manure is made. Lupins, which grow fairly well in a moist season on even the poorest of light soils, are excellent, if ploughed in green, as a source of both vegetable matter and nitrogen.

Ensilage.—As with the poor, heavy land, so with these poor, light soils it is probable that the introduction of modern methods of ensilage will lead to increased productivity. On poor, light lands, probably oats and tares, lucerne, sainfoin and maize are the most suitable crops to grow for ensilage. Maize, if well manured, grows with astonishing luxuriance on light land, and in a favourable season has grown as high as a man on horseback on land that is worth only a few shillings an acre rent. Silage would almost certainly render it possible to keep more live stock, and by so increasing the quantity of farmyard manure available would help to conserve the vegetable matter in the soil. Where leguminous crops were grown for silage the farm would be enriched in the nitrogen it so badly needs.

Potatoes.—There can be little doubt that, given suitable manuring, remunerative crops of potatoes can often be grown

on some of the moderately poor, light soils. In 1917, 16 tons of potatoes per acre were weighed on a poor, light soil which in all probability, in a normal year, would not yield more than 5 or 6 sacks of barley per acre, and probably not more than 4 sacks of wheat.

Potash.—The supply of potash in the quantities required is an insuperable difficulty at the present time. The figures obtained at Bramford show the great need for potash on these light soils, and there can be little doubt that potash is in many cases second only to lime in importance. Given an ample supply of these two plant foods, there appears to be no reason to doubt that, by making full use of the nitrogen-accumulating powers of leguminous crops, and by taking every possible opportunity of enriching the soil in vegetable matter, by folding sheep on the land, by ploughing in green crops, and by making as much farmyard manure as is reasonably practicable, the productivity of large areas of light land which at present contribute little or almost nothing to the food supply of the nation, could be vastly increased.

Artificial Manures.—Emphasis has been laid upon the importance of artificial manures in the improvement of poor land. These manures have sometimes been regarded as mere stimulants. This view is incorrect. There is no simpler or better way of increasing the productivity of a poor farm than the judicious use of chemical manures. By this means larger crops of straw, hay and roots, as well as of corn, are obtained, so that much more livestock can be kept and more farmyard manure is produced. In this way the fertility of a farm tends to increase.

The Influence of Livestock.—The influence of livestock upon the improvement of land is an important one. It is a matter of common knowledge that the more stock are kept on a farm the more corn it is likely to grow.

Pigs have been kept in enormous numbers in the past in Suffolk, and the manure they have produced has reacted most favourably upon the productivity of the land. They were fed largely upon imported foods, and their numbers have, of necessity, been much reduced of late. An attempt is being made by many farmers to keep on a fair stock of pigs by grazing them, or folding them on green crops. A number of breeding-sows were seen recently folded upon a mixture of trefoil, ryegrass and lucerne. They were in fair store condition and received nothing whatever but the green food and some whey. In all probability it will be necessary for some time to come to maintain our stock of pigs upon home-grown products to a

much larger extent than has been done in the past, but it is most important for the stock to be maintained at as high a point as possible, both from the point of view of our meat supply and of the fertility of the land.

Sheep are valuable because they produce both mutton and wool. The great benefits conferred by a flock of sheep upon light land have already been alluded to: they are kept upon the arable land all the year round and the skilled flockmaster grows a succession of green crops for their consumption. Sheep are also kept on heavy land, very profitably, by certain farmers. In the winter they live upon the grass land, whilst in summer they are folded upon the arable land. This proceeding undoubtedly has a most beneficial effect upon the soil. The manure also is produced where it is wanted—an important point in the case of fields some distance from the homestead.

Cows are increasing in Suffolk. After its productivity has been increased by basic slag, much of the poor, heavy land is essentially suited for cows. The growing of such crops as lucerne and tares enables a large number of cows to be kept on a farm with only a small proportion of grass. In districts near a railway it will no doubt be found most profitable to sell milk, but in the remoter parts cheese-making might be practised much more than is the case, either as a domestic industry or by means of co-operative cheese factories.

THE PROBLEM OF INCREASING THE AREA UNDER TILLAGE.—With the principal difficulty in this connection, that of labour, it is not proposed to deal here. There are, however, very serious problems involved in the actual finding of land suitable for breaking up.

As before stated, there were in 1916, 129,176 acres of permanent grass land in East Suffolk. Of this, probably quite 25,000 acres are marshes, *i.e.*, low-lying grass land, totally unsuited for the plough. Of the remainder, probably 50,000 acres are heavy land recently seeded down—land which was thoroughly farmed out when in arable cultivation and has now been allowed to go down to whatever grass it will grow. Since going down to grass the ditches have been in many cases neglected, and the land is now in a more or less water-logged condition.

If labour were available to clean out the ditches, mole-drain the land, and make a summer fallow of it with the aid of the steam cultivator, much of this land might, in a favourable season, yield 3 qr. per acre of wheat the first year, without any manure. If 5 cwt. of basic slag were applied in the autumn

and 1 cwt. of sulphate of ammonia in February, the yield might very well be increased under favourable circumstances to 4 qr. per acre, or even more. Subsequent crops would need to be continually manured, as the land is very poor.

In view of the scarcity of both labour and manure, the prospect of breaking up land of this type is not very attractive, either from the point of view of the farmer or of the nation. It is, however, probable that land of this type, which was under the plough until a few years ago, is less subject to wireworm attack than land which has been in grass for a number of years.

At the present time, when food is wanted immediately, the land selected for ploughing should be such as is likely to grow a good crop. With every prospect of scarcity of both farmyard manure and artificials, it is useless to expend what limited horse and man power is available on land which will grow very small crops. The amount of labour which must be expended on very poor heavy land is at least as great as that on better land. As much or even more seed is required, but the crop is only one-half. Of useful upland grass, which could have been ploughed up in the autumn of 1917 with a prospect of obtaining good crops without manure, or with very little, it is probable that not more than 50,000 acres were available in East Suffolk. Quite a large proportion of this consists of the two or three home fields clustered around the 3,000 home-steads of the county. It is evident, therefore, that the difficulty of finding the quota of grass land asked for was very considerable. The available land was very small in area, and much of it was so situated as to make it extremely difficult for a farmer to break it up. Every practical man knows how inconvenient it is not to have a few home grass fields in which to turn horses and other stock during the summer months. The industry of cow keeping, too, has made considerable developments during the past 20 years. Large quantities of milk are sent to London and to the East Coast seaside resorts. This adds to the difficulty of finding suitable grass land for ploughing without making inroads upon the essential industry of milk production.

GENERAL.—We have now considered in some detail a few of the problems arising in connection with the effort to make our country more self-supporting in the matter of food. An examination of English agriculture makes it clear that our land does not produce anything approaching the quantity of food which it might do. There are many causes for this: some of them political, connected with which problems arising

out of our system of land tenure and kindred subjects occur ; some economic, such as those connected with the period of low prices, in the " 'nineties." It is outside the scope of this article to deal with these problems. There are, however, other problems very difficult of solution which arise directly in connection with the cultivation of the soil. An endeavour has been made to point out some of these problems. One of them has not yet been dealt with, and that is, why one man should be a bad farmer and another man a good one. The problem is an important one, for it is probable that there is on an average at least one bad farmer in every parish in England. The chief cause of bad farming undoubtedly is the individuality of the man, but there are other causes.

The work of the War Agricultural Committees shows that there are many occupiers of land who do not understand farming. Many persons who occupy land have never had any training whatever in farming. They have had various other businesses, but for some reason or other have forsaken their first love, and followed after agriculture. Others have been brought up to farming, but, owing to lack of capital or lack of knowledge of the elements of agricultural science, or of opportunity of observing really good farming, have failed lamentably to make the most of their land.

This bad farming did not, perhaps, matter very much so long as we could import as much food as we wanted and had plenty of money to pay for it, but now things are different. The land of the British Islands is very limited in quantity, and the State has already decided that it is not in the national interest for men to neglect their land : many who have done so have been summarily ejected from their farms.

Since prevention is better than cure, it is obviously far better to do all that can be done to prevent the making of bad farmers in the future, than to be compelled to deal with them after their inferior methods have borne fruit. It would be a great advantage if the boys of the present generation, who will be the farmers of the future, could all have at least two years' practical training on the farm of a good farmer. A large proportion of the youths in question would get their training on the farms of their fathers. Those whose fathers were not good farmers would learn much by seeing better methods of agricultural practice elsewhere. All boys intending to become farmers would also greatly benefit by a training of at least six months' duration at an approved Agricultural College or Winter School of Agriculture.

Mr. Prothero* tells us that "in its hour of need agriculture found in Science its most useful help." As Science proved the friend of the farmer in the past, when the problem which confronted him was low prices, so she will prove his friend when the problem is how to produce food for the Nation, now and in the future. If our country is to be more self supporting in the matter of food, we must have a truly scientific agriculture—the best practice associated with science. It must be recognised that our best farming practice is widely different from our worst, and that a certain proportion of our worst farmers have neither practice nor science. To train up future generations of farmers so that they have at least a fair chance of learning both good practice and good science will surely be an important contribution towards the solution of the national problem of how to make the land grow more food for the people.

THE TAKING OF WILD RABBITS.†

PART II.

R. SHARPE.

FERRETING.—Taking Rabbits Without Cruelty.—The process of bolting rabbits by means of ferrets and catching them in nets as they seek to escape is considered by some to be the only really humane way of taking rabbits. The ferret and net system cannot be classified as a humane method of taking rabbits when they exist in a really wild state. Even though the ferrets are muzzled they scratch or "flog" any rabbit which is tucked up at the end of a hole until its back is quite raw. There is also to be borne in mind the fact that even a muzzled ferret must be allowed some play of the teeth, otherwise it will refuse to work. Even if the teeth open only a little way, there is sufficient liberty of movement to enable the ferret to bite a rabbit, the favourite hold under these conditions being by the eyelid. Evidence in this sense is obtained when rabbits so maltreated escape for the time being and are caught later on. The bite of a ferret resembles that of a rat, in the sense that the wound festers. Even in the case of a rabbit which has been "flogged" by a ferret whilst the rabbit is tucked up at the end

* *English Farming Past and Present*, Rt. Hon. R. E. Prothero.

† Part I. of this article appeared in the June, 1918, issue of this *Journal*.

of a hole, a "scab" as big as the palm of the hand is found on the back or rump, always, of course, assuming that the rabbit escapes at the finish. Much as I regret to say so, I fear that it must be admitted by all fair-minded persons that there is at present no known means of taking wild rabbits without causing a certain amount of suffering. Even when the gun is used there must always be a certain number which escape, to suffer a lingering death. Broken legs must cause pain until they become callosed, but it is astonishing how soon this process sets in. Clean and workmanlike killing on the lines I have endeavoured to expound in these notes is the only means I know of for giving effect to humane intentions.

Value of a Good Terrier.—Good terriers or spaniels are of very great value in dealing with rabbits, for they often save a lot of valuable time and labour in locating ferrets and rabbits underground. A dog of the right stamp of intelligence will very soon become "true to hole," unerringly marking any small hole that contains a tenant and being equally certain of passing by those which are unoccupied. This alone saves much loss of time. A good dog will soon learn to pounce upon a rabbit that bolts into the net, and so prevent its escape, for no matter how carefully purse-nets are laid loose sticks and brambles often prevent a rabbit-tight joint being made. A dog which has learnt this accomplishment should always be allowed to sit on the top of the burrow, the position allotted being for preference fairly central, to enable the dog to signal the first move of the rabbit or the action of the ferret in striking at it. The dog moves its head in listening to the underground movements. As these make a rumbling apparent to the human ear, how much more must they tell to the acute senses of the dog?

Ferrets on Line and Free.—Some rabbit-catchers use nothing but the line ferret whilst netting, but my own practice is to rely more particularly on a loose, muzzled ferret; the reason being that if a rabbit is at all inclined to bolt, a ferret unhampered in its movements may follow it up more quickly and so at once bring off a capture. A line ferret by contrast may find a difficulty in pulling the line sufficiently quickly round twists and turns to keep the rabbit on the run. Even when rabbits are not bolting well the loose ferret will drive them into blind alleys, where, perhaps, the whole contents of the burrow may be collected. A single digging will then bring a nice haul within arm's reach. Should a line ferret be used in similar circumstances, it will kill the rabbits singly as it rounds them up

one by one, and as many separate diggings will be called for. The line ferret is nearly always a big, powerful chap, usually a certain killer, as all good ferrets should be. For my part I do not care for a big ferret for use on a line. The idea that such is necessary may be assumed to follow from the belief that its greater strength enables it to pull the line round corners. But the trouble comes in when the line ferret kills a rabbit in a narrow part of the burrow, often in a place where it cannot be recovered without hours of labour. In such cases one would prefer to pull the ferret out and proceed to a fresh spot, but the size of the ferret prevents it passing beside the rabbit in response to the pull on the line. All told, a small ferret is to be preferred for line work. Not only can it be got away quickly from a kill, even when it has passed beyond it, but, in addition its slender dimensions enable it to climb over a rabbit and get at the head. This is often a help, for the rabbit may be driven back towards the mouth of a hole.

Ferret Line.—I mostly use a line six yards in length. If made of proper material any ferret can drag it along for the full length. Failures in this respect are often caused by the line not being paid out sufficiently freely. A single moment's tightness will cause the line to cut corners, so entering crevices or cutting into the earth in a manner which multiplies friction. Too loose a line is also to be avoided, because the loops which are then liable to form may get entangled round rocks or root stumps. The happy mean is attained by allowing the line to run freely through the finger and thumb of the right hand, the contact so established with the ferret permitting all its movements to be noted. For instance, preparatory to striking at a rabbit a ferret always make a stop. The novice will learn to detect these symptoms just as an angler can tell from the sensations conveyed through the rod what a fish is doing with the bait. There is nothing I like better for a ferret-line than a good class of blind-cord of medium thickness. The fact of its being plaited gets rid of the tendency for kinks to form, these being associated with every kind of twisted rope. Such a line will last an entire season, assuming any ordinary amount of work; that is to say, it will suffice for the man who, working with traps and snares, turns only to ferrets and nets or gun when weather brings the other methods of capture to a standstill. An alternative to blind-cord is a length of round lamp-wick of the kind which is used for the cheap paraffin lamps which are to be seen in cottages. Being made of plaited cotton the wick is very flexible.

Marking the Line.—It is always advisable to have the line marked so as to show the whereabouts of the ferret. The first mark should be placed at 18 in., the next at 1 yd. and the others at yard intervals to the end of the line, each mark to be distinguishable from the others in the manner of the fathoms on a "log." Many men simply knot the line; but this is wrong because it spoils free running, and will act as a solid stop if the line enters a crevice or an angle formed by tree-roots. There are many such places in rabbit-holes. Arduous digging is the final penalty for any time saved by marking the line with knots. The best plan is to affix the marks by working thread in amongst the cord strands, using a needle for the purpose. The loops should be left long, so that when cut off they form tassels. These offer the least possible resistance to the free motion of the line. Such marks are invaluable as an indication of the position of the ferret and the amount of top earth that needs removing to reach it.

Muzzling Ferrets.—I prefer to use a home-made string muzzle for this purpose, never those of the metal or leather kinds, which do not stay in their proper place, while the metal ones cause discomfort to the ferret, and any irritation of this sort interferes with its proper working. When wearing a properly-attached string muzzle a ferret will work with comfort and keenness. The contrivance is easy to make, ordinary white kitchen string being the best material to use in making it. To prepare and fit a muzzle, take two pieces of string, from 12 to 14 in. long, lay them together and knot them (as if they were one) about 6 in. from one end; then form a similar knot about three-quarters of an inch away from the first (or 1 in. for a long-headed ferret); after that bring the two longest ends, necklace fashion, round the ferret's neck, making a knot on top, and leaving the first-made pair centrally below. A second person holds the ferret round the shoulders whilst all this is going on. The two other ends are then pulled forward so that the second of the pair of knots is drawn under the ferret's chin; the free ends of string are then brought around the ferret's muzzle (snout), so that they meet on top, where they are tied; the final knot, joining the four free ends of string is then made between or slightly above the ferret's eyes. A muzzle so made, with the various parts drawn to the required tightness prior to locking the knots, acts perfectly. In trimming off the loose ends they should not be cut too close for fear a slight drawing of the knots may untie them. When the day's work is done the muzzle should be removed by cutting, fresh string being

required for each occasion. I have known and tried many other ways of making muzzles, but the above has been proved by continued test to be at once the most serviceable and, for the ferret, the most comfortable. Muzzling ferrets by sewing their lips together is vilely cruel, but fortunately the practice has no utility to recommend it.

Recommendation of a Spear.—Among the accessory tools of ferreting none is more useful than a spear. It is made of a round bar of steel pointed at one end and at the other bent in the manner of a meat-skewer to form a handle. Its length is about 3 ft., and the diameter a full three-quarters of an inch. No man who ferrets regularly should be without this implement. With it he can locate a hole underground by pressing it into the ground, in just the same way in fact that mole runs are found with a walking-stick. A certain amount of caution is necessary in prodding at ground which is supposed to overlie a hole, for if too much force is used the sudden jump which occurs when a cavity is entered means that the spear drives in so quickly that it may impale ferret or rabbit—that is if a kill happens to be going on just below. With a little practice the hole can be felt for quite slowly, with the result that rabbit or ferret, as the case may be, gets pushed out of the way. When an extra deep dig is in prospect the spear saves a lot of trouble, for by exactly locating the hole it gets rid of the annoyance of occasionally digging deep down and finding at the finish that the hole sought has been passed on the way, perhaps the thinnest of partitions hiding it from view. This is especially liable to happen when, the ferret having already killed the rabbit, there is no sound to guide the digger. The sole noise then remaining is that the ferret makes whilst eating the rabbit, and the ferret is not noisy in taking its food.

The Ferreting Spade.—Two sorts of spades, or grubs as they are often called, are required when ferreting. My selection has always been, first, a short-handled spade for ordinary digging, and, second, the long-handled Norfolk graft or digger. This last is a really wonderful implement, and the most useful of all the spades which have ever been proposed or made for digging out rabbits. The one I use is 7 ft. in length, and it carries at one end a small scoop-shaped blade, and at the other a crook, or it might be called a hook. Tremendous purchase is given by the great length of shaft, and the entire weight of the body can be thrown into digging in most difficult places. The crook is invaluable for drawing out dead rabbits beyond the reach of the arm, also for drawing up the line when its presence

has been detected far away from the hole where the ferret was first inserted. When a hole has been broken into, the blade of the spade should be exchanged for the crook end, which may be used for raking the bottom of the hole. If the line is touched its presence can be felt, and it may be drawn up from depths otherwise beyond reach. In digging with this spade the hole should be made at a slope of 30 to 35 degrees, care being taken to keep it about the size of the spade, so that in drawing back the spoonfuls of earth none will fall off the sides. The upward tilt of the blade assists this removal of material from steep-angle holes. With a very little practice depths of 5 or 6 ft. can be penetrated, rabbit and ferret being drawn out with the aid of the crook. Longer shafts can be laid on these spades than that named, but they are only needed on the sand hills of the Eastern Counties.

Nets.—In selecting the kind of net to use for taking rabbits, regard must be had to the nature of the burrows that have to be attacked. Where only small breeding holes have to be dealt with, or burrows having half-a-dozen outlets—say twelve as a possible maximum—then I should plump for the purse-net. These should be of an ample size, and have reins running right round them, with a peg at the extremity, so that they may be securely fastened. Small purse-nets are the cause of a lot of losses, as they are somewhat easily knocked on one side. Good, sizable nets are also quicker to lay. They must be made with proper netting string, otherwise they kink and twist into all sort of shapes. The right size of net made of the right material will hold "Bunny" without hope of escape. When netting the large burrows which are to be found on the commons of such counties as Dorset and Hants, and the downs of Wilts and Sussex, what are known as "flambs" are, perhaps, to be preferred to purse-nets. To stop each hole with its own separate purse-net requires a lot of time. In saying this I have in mind burrows with anything up to 100 or 150 outlets. "Flambs" are simply square nets with the meshes gathered across each end and tied. They are about 3 ft. square, and are laid loose over the holes. A large number can be laid in a comparatively short time, owing to their size and the fact that no pegging is required. Care must be taken to remove any loose sticks away from the front of the holes, otherwise they hold the net in one place so that the rabbit is able to disentangle itself. When using flambs a good dog is essential, for unless a rabbit is pounced upon, the moment it becomes entangled in this unexpected obstruction it will soon struggle free.

Digging Operations.—Though much was said about digging when describing the spade, some special remarks are desirable apart from that connection. Ferreting mostly resolves itself into dealing as quickly as may be with the unavoidable interruptions to smooth working. As soon as a ferret is judged to have made a kill underground, the tendency is to start in haste digging with the spade. The disturbance so caused may induce the rabbit to make violent exertions to rid itself of the ferret, and this it often does. Even when the worker is certain that the ferret has gained a firm hold, he would do well to take a little time to locate the exact spot. This can be done by placing the ear to the ground, but even better is to plant the spade in the earth near where the rabbit is thought to be and to place the ear on the top of the handle of the short spade, or at the side of the long one, if that is in use, and to listen carefully. The sound is conveyed very clearly through the spade-handle so that with a little practice the novice can soon learn to locate the exact position. If the sound is judged to be insufficiently clear at one place, the spade may be moved to another and the test be repeated. The point where the sound is most clearly heard will, in that way, be quickly decided. If the rabbit is still struggling, the bumping is felt as if it were actually at the end of the spade itself. The more usual method of placing the ear close to the ground is all very well in a dry season, but when snow is about or when working on wet clay the sounding post is to be preferred. When the hole has been made and the rabbit removed the ferret should be carefully drawn out and its feet be thoroughly cleaned. It is then ready to be put back into the same hole. The precaution of cleaning the ferret's feet should never be omitted, for if there is another rabbit at the end of the hole and the ferret cannot get at its head, rump-scratching will be immediately resorted to. The fresh supply of fur so collected on the ferret's front feet will thus give information which would not be available if the ferret had been returned to the hole with fluff from the previous rabbit still adhering to its toes. Should the hole be empty, that fact is also made obvious.

Always Fill in after Digging.—The mention above of large burrows involves a stern warning to all persons engaged in ferreting as to the necessity of making good any disturbance caused by digging. If that is not done large burrows become larger by the constant opening up of new communications, and they soon pass beyond manageable limits. I always make it a strict rule to fill in afterwards all holes that have been dug out, firmly treading down all the returned earth. The prompt

repair of all disturbance caused by digging soon brings fresh tenants to the burrow ; but if it is left, as I fear is too often the case, months may elapse before the rabbits again take up their abode in their rudely-disturbed quarters. Rabbit earths, to be snug and warm, must possess a suitable system of ventilation ; and there can be no doubt that the piercing of new exits and entrances will upset the plans made. Before the home is again suitable for occupation the existing system of holes must be extended, new openings made, and so on. If a human dwelling-house had a hole pierced in the roof either it would have to be repaired at once or fresh apartments would have to be provided. For the rabbit, extensions are the only resort.

Ferrets Lying Up.—At times a ferret will lie up in a position from which it cannot be recovered by digging. When this happens all holes should be made secure, and in the mouth of the one from which the ferret is judged to be most likely to emerge should be placed the ferret bag containing a nice straw-bed. A rabbit's paunch should be placed beside the bag so as to provide a definite lure. When all is complete this hole also should be stopped so that the ferret cannot by any chance escape. Nine times out of ten the ferret will be found next morning snugly curled up in the prepared bed. Should the odd occasion arise, a line ferret should be run into the hole, as there is a possibility that a rat or rabbit nest may be the chosen place of rest. Usually the line ferret will disturb the sleeper, so that it follows its companion when the line is drawn in. The waiting tactics may often be avoided by having available a few blank cartridges loaded with a liberal charge of black powder. No stopping of holes is in these circumstances necessary. The muzzle of the gun should be held 4 or 5 in. away from the selected hole, the discharge carrying the smoke well into the hole. A turf should at once be placed over the opening to give the fumes an opportunity of penetrating to the utmost recess of the burrow. As no animal likes smoke, the ferret will in all probability abandon its idea of taking a rest and make a hasty exit *via* one of the available side doors. Another excellent plan for inducing a ferret to leave a hole is to paunch a rabbit whilst quite hot and at once to place the attraction in a hole specially chosen, so that the wind may waft the odour into the burrow. Few ferrets are able to resist such a lure. Yet another plan is to wind the thin part of a rabbit paunch on the end of a long stick, and push it right down the hole. When the ferret nibbles the bait the tug is immediately felt, and the "line" may be drawn in gradually until the ferret is within reach.

When Ferrets Must Not be Used.—The use of ferrets after the rabbit-breeding season has commenced is not to be recommended for several reasons, unless, of course, no other means of capture are available. When rabbits have begun to breed the bucks become what is termed "rank." This a ferret does not like, and although it may work for a time early in the day when stimulated by hunger it soon tires of the objectionable task. At the season in question the does very often take refuge in the blind ends of holes, so as to be able the better to protect themselves against the worrying attentions of the bucks. For this reason the bucks are generally first encountered by the ferret, the two being thus driven into a corner, so to speak, with the doe at the back. The doe which is not rank is thus screened by the buck, and apart from the ferret's natural disinclination to tackle the buck at such a season, the buck indulges in a peculiar system of warfare to which the ferret has a strong aversion. Literally it sprays "urine" in the face of the advancing ferret. Confirmation of the belief that the bucks are the difficulty is to be found in the fact that four out of every five rabbits taken at such seasons are does. Favourable conditions for improving the quality of stock only exist when the surplus of bucks can be removed, and the curious circumstances related in this note go to show that ferreting left till too late in the season accentuates the evil of a surplus of bucks.

Shooting Bolted Rabbits.—So far I have only dealt with ferrets when used as a means of driving rabbits into nets. When using them for bolting rabbits for shooting, careful attention must be paid to wind direction. Otherwise good results cannot be expected. A most excellent way of deciding the direction of even the gentlest breeze is to pluck a fluff of rabbit hair from one already bagged, and to note which way it drifts when released from finger and thumb. No matter how slight the air movement may be any human contamination will be circulated in the burrows below ground, so giving warning to the rabbits that danger threatens. The novice-shooter who studies his own comfort regardless of the effect produced will nearly always take his stand in a position which enables him to turn his back to the wind. As he must face the burrows, he unconsciously gives the rabbits his "wind" from the very commencement. Good results require from the shooter that he shall face whatever wind is blowing, otherwise the rabbits will promptly retire to the depths of their holes, and will take their chance with the ferrets rather than show themselves above ground. A hedgerow should always be worked

up wind if the air-current is in the slightest degree up and down. For ferreting with the gun a dog with thorough mastery of the duties required is most useful. It will often save hours of digging by promptly securing wounded rabbits which would otherwise struggle into a hole. So serious are the delays occasioned by putting ferrets into holes known to contain wounded rabbits that those out for sport alone often fall under the temptation of passing by such places. A wounded rabbit will not only itself refuse to budge, but the others in the same burrow become equally obstinate. A ferret which is put into a hole containing a wounded rabbit will attack it in preference to any others that may also be present. Digging is thus nearly always necessary ; so that a dog of the right stamp and training adds materially to the day's results. Burrows to be ferreted should always be approached in the stealthiest possible manner, conversation, of course, being avoided, as well as all unnecessary movement. On no account should the ground be walked over beforehand, no matter how great may be the desire to obtain a general geography of the burrow. Such surveys are at all times unnecessary, because the ferret should always be introduced at the first hole on the outer edge of the burrow. Having the wind in its face it will at once scent any rabbits which may occupy the hole. A very common mistake made by an astonishing number of those who follow this sport is to give vent to their impatience and excitement. Without realising the harm they do, they chatter and argue over the burrow, perhaps in an endeavour to force the ferret to enter a particular hole. Absolute quietness is essential, simply because the whole spirit of ferreting is to make the rabbits believe that the foe which attacks them in their home is the only one they have to fear. If given no reason to think otherwise, they instantly seek safety in flight.

THE following statement published by the Department of Agriculture and Technical Instruction for Ireland was received too late to be included in the June issue of this *Journal* :—

**Ireland as a
Food Supplier of
Great Britain.**

With a view to encouraging the Irish agriculturist by bringing home to him the part he is playing and can still further play in food production and, incidentally, the importance of the market at his door, and with the object of making better known in Great Britain the place Ireland is taking as a supplier of food for the British population and the Allied Armies, the Department think it desirable to publish the following particulars :—

I.—The Importance of the Irish Food Supply.—Ireland's production of food, including especially her supply of food to Great Britain, has for

several years past, under the system of agricultural education and administration introduced by the Department of Agriculture and Technical Instruction, been steadily growing, until *the supply from Ireland has become the most important in point of quality, character, and proximity, arriving in Great Britain from any country in the world. Since the War that supply has been fully maintained.*

By 1913 Ireland's supply to Great Britain had reached a point where it was only exceeded by that of one other country in the world, the United States of America. Since the War the supply coming from the United States has abnormally increased, and the Irish supply, though not in this proportion, has gone on increasing during these years also. The following figures illustrate this position :—

Values of Food and Drink Stuff's Imported into and Retained for Consumption in Great Britain from the undermentioned Countries.

	1912. Millions	1913. Millions	1914. Millions	1915. Millions	1916. Millions	
Ireland ..	£ 30	£ 36	£ 37	£ 46	£ 59	
United States ..	30	39	42	82	116	
Argentina ..	31	31	27	46	36	Values
Canada ..	18	19	23	27	41	for
British India ..	22	17	13	22	20	1917
Denmark ..	20	22	23	20	20	not
New Zealand ..	9	9	11	16	18	available.
Netherlands ..	14	16	17	14	13	
Australia ..	13	15	16	12	10	
Russia ..	17	15	13	8	1	

II.—Maintenance of Supplies since the War.—(1) *The Irish Supply.*—

Taking quantities instead of values, and comparing the average of the two pre-war years of 1912 and 1913 with the average of the last two years, 1916 and 1917, we find that Ireland exported to Great Britain the following quantities of foodstuffs :—

			Average. 1912-13.	Average. 1916-17.	Percentage. Increase (+) or Decrease (-).
Live Cattle	832,000	889,000	+ 6·9
„ Sheep	639,000	700,000	+ 9·5
„ Pigs	233,000	239,000	+ 2·6
			<i>Cwt.</i>	<i>Cwt.</i>	
Butter	750,000	720,000	- 4·0
Eggs	1,120,000	1,380,000	+23·2
Poultry	300,000	290,500	- 3·3
Bacon and Hams	1,220,000	1,080,000	-11·5
Oats	1,340,000	1,700,000	+26·9
Potatoes	3,000,000	3,460,000	+15·3
Biscuits	340,000	420,000	+23·5
Yeast	140,000	220,000	+57·1
Condensed Milk	260,000	240,000	- 7·7
Forage	485,000	726,000	+50·0

It will be seen that the items in which there is a net decrease, viz., pig-products, dairy produce and poultry, are those directly affected by the reduction of the import into Ireland of feeding stuffs from abroad, such as maize, cattle-cake, etc. Ireland normally imported about 800,000 tons of these feeding stuffs annually; in 1917 the import was reduced

to 500,000 tons and has since almost ceased. This loss of imported feeding stuffs, although partially replaced by home-grown, is bound to affect both the live stock and live stock products. The above rate of export of live stock in 1917 to Great Britain has only been given at the cost of a draft upon the capital reserves of live stock. At the same time, notwithstanding the reduction of imported feeding stuffs and the withdrawal from grazing of 637,000 acres of grass (ploughed in 1917), Ireland has maintained her live stock export; while in addition, out of her 1917 crop she has supplied to date (May, 1918) to Great Britain and to the Army: 5,100,000 cwt. potatoes; 900,000 cwt. hay and straw; 1,700,000 cwt. oats, and has furnished 600,000 cwt. oats for manufacture into oatmeal.

(2) *The Supply from other Countries.*—Taking as near as possible the foodstuffs imported from all foreign countries and British Possessions into Great Britain (imports into United Kingdom minus total imports into Ireland) we get the following figures (the classification is not the same, but it is the nearest possible. The figures are the latest available published figures):—

	Average. Tons. 1912-13.	Average. Tons. 1916.	Percentage Increase (+) or Decrease (-).
Beef, fresh	423,000	353,000	- 16.5
Mutton, Fresh	256,000	182,000	- 28.9
Pork „	20,000	15,000	- 25.0
Meat, preserved (mostly Tinned Beef)	44,000	94,000	+ 113.6
Butter	201,000	107,000	- 46.8
Eggs	180,000	51,000	- 71.7
Bacon and Hams	252,000	407,000	+ 61.5
Potatoes	373,000	85,000	- 77.2
Condensed Milks.. ..	57,000	65,000	+ 14.0
Margarine.. ..	68,000	130,000	+ 91.2
Wheat	5,003,000	4,620,000	- 7.6
Wheat Flour	310,000	256,000	- 17.4
Barley	997,000	718,000	- 28.0
Oats	890,000	617,000	- 30.7
Rice	204,000	425,000	+ 108.3
Maize	1,614,000	1,198,000	- 25.8

III.—*Great Britain's Nearest and Greatest Food Base—Its Importance Enhanced by Present Position of the War.*—Ireland, it should be observed, grows more food for Great Britain than she does for herself, even proportionately to her population. This is her main agricultural business.

She is, in an increasing degree, *an essential base*, not only for the British food supply, but for *British agriculture itself*, whose meat-raising and dairying depend on Ireland's breeding and production.

Although having only 10 per cent. of the population, Ireland produces 40 per cent. of the cattle and 30 per cent. of the pigs of the United Kingdom.

She consumes only one-fourth of her own cattle. The rest are for Great Britain. Of the beef cattle, two out of every five killed in Great Britain were bred in Ireland.

These facts are perhaps sufficient to illustrate Ireland's importance as a food base.

But with the present position of the War, American tonnage required for the transport of troops and munitions, and the difficulties of the ocean journey for food cargoes, the importance of this food base at Great Britain's door is enormously enhanced.

IV.—Results of Compulsory Tillage Scheme.—To meet the new position of the food supply in 1917, the Department, following the appeal of the Prime Minister and the Food Controller, asked the Irish agriculturists to put forth a special effort of war food-production by breaking up an extensive new area of land.

At the same time the Department obtained a Defence of the Realm Regulation making it obligatory on any occupier holding more than 10 acres to break up at least 10 per cent. of the arable area of his holding in addition to the amount under cultivation in 1916. This compulsory power had only to be exercised in an insignificant minority of cases.

The response of the farmers was spontaneous, and with the aid of organisation through their existing County Committees of Agriculture, etc., under the system of the Department, the result given was remarkable.

Within the space of three months a total new area of 637,000 acres was broken up by the plough and put under food crops.

A new Food Production campaign has been opened in 1918, and *it is the estimate of the Department that the extra war food-production of 1917 will be far exceeded.* The new area under the plough in Ireland should prove to be well over 1,000,000 acres—and may even be 1,500,000 acres—more than the amount cultivated in 1916.

V.—Orders Regulating Export and Import between Ireland and Great Britain.—Some explanation as to the meaning of certain Orders which have been issued recently regulating exports from Ireland to Great Britain and *vice versa* seems to be called for.

These Orders have dealt with, at various times, the export of potatoes, of oats, of breeding stocks, of butter, etc., and an impression has gone abroad that Ireland, by these Orders, was selfishly retaining food within her shores and not allowing it to go to Great Britain.

The fact is (1) that *most of these Orders*—which were, moreover, not Orders merely prohibiting export, but regulating export under licence—*have been designed for the common interest of the United Kingdom*; and (2) that they have been either imposed *after consultation with the Food Controller*, or have been imposed *at the instance of the Food Controller*.

The object of some of the Orders—those dealing with bacon and butter are examples, they were imposed by the Ministry of Food—was *to save tonnage, in accordance with an arranged plan*, by a temporary substitution in each island of a supply customarily imported by a supply customarily exported; or, as in the case of potatoes, *to regulate, also by arrangement, the exportation of the produce to or from particular districts.* As Ireland imports a proportion of her own food supply there is material for a certain amount of substitution of this kind in war circumstances.

The Order dealing with butter, for instance, enacts that Ireland, during the winter months, when her own production is short and she supplies herself largely from imports from the Colonies and Denmark, should get no imports, but retain her home-produced butter, Great

Britain taking the imports usually going to Ireland. Export of butter has now been resumed in accordance with plan.

The object of other Orders, such as those dealing with cows in calf, milch cows, heifers, breeding sows, breeding ewes, etc., is to *conserve the breeding-base* of the live stock from dangerous depletion. Reference to the facts cited above as to the rôle of Ireland as a breeding-base for Great Britain will show that these are Orders absolutely *in the interests of the United Kingdom as a whole*. The supply of live stock to Great Britain for beef, mutton, milk, butter, cheese, pork, and bacon would fall to a disastrously low point, from which it could not be recovered for years, if this case of the breeding-animals was not vigilantly watched in all three Kingdoms. And, again, these breeding-stock Orders *regulate export under licence*, so that the export is not completely stopped, but is allowed periodically or all the time in greater or less extent, according to circumstances.

Almost all of these Orders, after they were enforced, came to be misunderstood in Great Britain, until a general impression that Ireland was selfishly holding up food supplies has been the outcome. The figures quoted in this statement show that there has been no such holding back of supplies. The Orders, the working of which has given rise, owing to misunderstanding, to the wrong impression just mentioned, are intended to secure that Ireland will be in a position to continue, to the fullest possible extent, her contribution of necessary food to Great Britain.

IN Germany and the Scandinavian countries especially the very serious shortage of fodder has forced the authorities to utilise any plant material that can be easily obtained.

Fodder Substitutes: The large quantities of wild vegetation, such as heather, bracken and seaweed, which are available, have made it worth while to experiment extensively on their possibilities. The

How Wild Vegetation is Utilised in Other Countries. French, who are now experiencing shortage, particularly of oats, have issued very careful directions and analyses concerning seaweed, chestnuts and acorns, and vine-leaf cuttings. Very fibrous and woody material can be used by animals if the cellulose of which it is composed is finely divided first; but it will not form a food that is quite satisfying, nor will it be fattening or conduce to yield of milk. The utilisation of apparently impracticable cellulose has been carried by the Germans, and by the Swedes following them, to the extent of making fodder from wood pulp. The treatment of the cellulose in this material to make it digestible has been successful enough to tempt experimenters to try to adapt it for human consumption.

Heather.—Heather has been used in Germany quite extensively since 1916. It is mown, then chopped and dried. The leaves and flowers are stripped from the woody stalks, and these are then ground. This is Heather Meal I., used mixed with molasses and some albuminous material to fatten pigs. Still green stems containing little wood are ground into Heather Meal II., used for horses and cattle when mixed with molasses. Last year some heather was imported from Holland, and the industry in Germany seems to have spread. In a private letter from Neugraben (east of Berlin), October, 1917, the writer speaks of having acquired 3,000 acres of heath at 7s. per acre; 1d. per lb. was paid for the heather in pieces 6 in. long.

In Sweden the Fodder Bureau created, in November, 1917, a Heath Bureau to promote its collection, with headquarters at Christianstad in the extreme south. Last autumn the Government authorities ordered 30 metric tons, after some experiments on army horses, who ate it willingly. The experimenters stated that if harvested in the early flowering stage, with the least amount of wood possible, its food value was estimated as half that of hay; but the directions of the Bureau issued this spring are that it is to be gathered dry, not wet or frozen, and that it is "equivalent to good straw." The trade is at present uncontrolled, but the Bureau pays at the rate of $\frac{1}{2}$ d. per lb. Two Swedish chemists who are taking out a patent for fodder cake use "heather meal."

Danish heather used to be exported, but during 1917 it has been extensively used as fodder in Jutland, Zealand, and Copenhagen. It is used directly for horses and cattle; but the Aarhus Oil Mills and the Danish Soya Cake Factory have a process of drying and crushing it and then mixing it with molasses. It is used in the army as both feeding and bedding stuff; also for firewood. Further, it is made into briquettes for fuel. There is a report that the Aarhus Oil Mill is experimenting in the manufacture of tea from heather. Denmark, however, possesses only a small area of heath land, which is being rapidly stripped.

The Austrian Central Food Bureau is this year buying large quantities of heather in Russian Poland, as experiments with it have proved satisfactory.

Bracken.—In Sweden experiments were made last summer in feeding army horses on bracken at the same time as on heather, but the results were not so good, although the horses would eat it dry. Further experiments were to be put in hand. The roots are extensively used to make a coffee substitute, being very carefully dried and then roasted. In Austria the root of the Eagle fern (*Pteridium Aquilinum*), which grows as a weed in Croatia and Bosnia, has proved an excellent fodder for pigs. In the spring of 1917 the military authorities offered 6s. 3d. per metric cwt. for air-dried, purified sound roots. It was stated that a ration of $4\frac{1}{2}$ lb. was ample for a full-grown pig.

Seaweed, etc.—Thorough investigation was made in France in May and June, 1917, on the use of the laminaires, which are common on the Breton coast. The general results were communicated to the Académie des Sciences early this year. Analysis showed the following figures:—

	Prepared Seaweed.*		Oats.	
	Per cent.		Per cent.	
Water	14.40	..	12.55
Carbohydrate matter	52.90	..	66.80
Nitrogenous	17.30	..	9.10
Cellulose	11.50	..	8.45
Mineral matter	3.90	..	3.10

Experiments show that as a feeding stuff 3 lb. of the seaweed material* were equivalent to 4 lb. of oats. Horses suffering from lymphangitis (an epidemic disease which is rife among wounded horses at the front) improved under this diet, and the disease disappeared. This action has been attributed by Lapicque and Legendre to the trace of iodine present; but this statement needs further evidence.

In Germany the State has monopoly rights on imports of seaweed. Grass wrack (*Zostera marina*) and bladder wrack (*Fucus*) have been

* The analysis clearly points to a dried preparation. See the Board's Leaflet No. 254 (*The Use of Seaweed as Manure*).—Ed.

generally used as fodder since 1916. In September, 1917, a factory was erected in Schleswig to treat seaweed by a new process. In October, 1917, seaweed was sent from Holland to the German troops in occupied France, but according to a captured official document it was there being used as a substitute for mattresses. In January, 1918, directions were issued for the collection of sea grass (*Carex bucooides*). An embargo is placed upon it; the quantities cut must be reported quarterly to the Central Office for Straw Substitutes. In France grass wrack is used.

Reeds.—In France a Ministerial Circular in July, 1917, recommended the use of fresh reeds for pigs. A reed-flour for fodder was put on the market in February, 1918. Reeds of the genus *Arundo* are dried, then pulverised and sieved. Analysis gives :—

Fatty material	10 per cent.
Nitrogenous matter	16 „
Carbohydrate „	15 „

which puts it between medium hay and very good straw. In August, 1917, the Swedish Government ordered the harvesting of all rushes by the owners on pain of expropriation. The German Government last autumn recommended the use of *young reeds* as hay, or converted into flour. The reed-hay is stated to be of good digestibility, equal to that of winter straw, and containing a little more protein.

The analysis of the War Fodder made from young reeds is given thus :—

Water	8.98 per cent.
Raw protein	8.63 „
Raw fat	1.18 „
Non-nitrogenous products	43.17 „
Raw fibre	28.97 „
Ash	8.07 „

It is sold at 28 M. per 100 kg.*

Mention is also made of the sea-rush (*Bolboschænus maritimus*), of which the part above the ground has the same value as straw, but the tubers are equal in value to horse-chestnuts; and of the pond bulrush (*Schænoplectus locustus*), the horizontal roots of which form good starchy fodder.

Leaf-fodder and Twigs.—The use of foliage, twigs, and young shoots of any trees and shrubs has been largely developed in Germany since 1916, when it was spoken of as greatly neglected. An Order about the collection of leaf-hay and twig-fodder was issued last December, and further directions given in February. All trees and shrubs may have their cuttings utilised except bird-cherry, laburnum, ivy, acacia, alder. Another set of directions recommends acacia and alder, with ash, poplar, birch, lime, beech and hazel-nut, also fruit trees and shrubs. The material should be collected in winter, before the buds burst. Sheep and goats can eat it unchopped; for other uses it should be cut fine in a chaff-cutter and used wet or dry; but it must be kept dry if preserved at all, otherwise it will mildew. This year it will be collected officially; owners of gardens, woods and parks, and the administrators of State forests are enjoined to organise the cutting and collection. In Austria the Fodder Substitutes Department offered in February, 1918, to purchase cuttings from ash, poplar, birch, lime, copper-beech, aspen, hazel, hornbeam and redwood. It is recommended that these

* Say 14s. 3d. per cwt. at 1 M. = 1s.

should be pounded and ground. In France directions are given only for vine waste, with the following analyses:—Branches, equivalent to ordinary hay, 7-8 per cent. nitrogenous matter; leaves, 13 per cent. nitrogenous matter, 4 per cent. fatty matter, 60 per cent. extractive matter other than nitrogenous. Branches should be crushed and kept out of contact with air. "Leaf-fodder" is also used in Denmark.

With regard to acorns, horse-chestnuts and seeds of forest trees, the Ministerial Circular of July, 1917, to the French Prefects gives full information.

Acorns may be eaten by all animals as follows (if the amounts are exceeded enteritis and albuminaria may result):—

			<i>Fresh Acorns.</i>	<i>Dry Acorns.</i>
Horses of 1,220 lb.	8½ lb.	5½ lb.
Bullocks 1,320 to 1,540 lb.	13½ "	7½ "
Milch cows 1,220 to 1,320 lb.	6½ "	5½ "
Sheep	1½ "	1½ "
Pigs	3-3½ "	1½-2½ "

For horses 7 pints acorns are equal to 5½ pints of oats. Acorn feeding should be suspended for a week after a month's continuous use. Horses and cattle should have raw acorns crushed and the husks removed. For pigs the acorns should be crushed into a coarse meal and mixed with cooked potatoes, or cooked with potatoes.

Horse-chestnuts.—For sheep especially 1 lb. to replace 3 lb. fodder beet. The maximum ration should be 2 lb. Cattle may receive 4-6 lb. for fattening purposes. The chestnuts should be cooked or cut up and well mixed with other food. Pigs refuse them in all forms, and they are poisonous to poultry, ducks and game.

In August, 1917, it was announced that a Danish company was being started to make the seeds of all wild trees—beech-mast, maple seed, acorns, etc.—into an oil-cake, but no further information has been obtained.

In Austria all horse-chestnuts and acorns were requisitioned in September, 1917. In Norway farmers were advised last February to use them. Beech-nuts are certainly collected in Germany; but horse-chestnuts and acorns are needed for coffee substitutes.

Potato-tops were recommended in Norway last September to be used mixed with other fodder because of the large proportion of ash. The analysis is given as water 15 per cent., ash 16.4 per cent., fat 2.7 per cent., protein 14.8 per cent., non-nitrogenous extract 31.9 per cent., vegetable fibre 18.2 per cent. (this is doubtless the dried tops).

In Germany the *beet-root leaves* at the sugar factories are dried, giving a yield of 1 cwt. dry for 5 cwt. wet; and other root-crop leaves are similarly dried with a yield of 1 cwt. for 10.

Hazel-catkins are being used in Germany as a substitute for bran. Directions were issued in January, 1918, that they should be collected in March before the blossoms burst out, well dried on the top of stoves or ovens, and milled or pounded into flour. The flour should be given dry, or sprinkled on rough fodder with some salt, not put into drinking water. Small quantities should be given at first to prevent indigestion; the maximum amount should not exceed 4½ lb. daily. Birch, alder, or beech catkins may be tried.

Considerable attention is being paid to *Pine and Fir Needles* in Sweden, since analyses show that protein, starch, dextrin and sugar are present in considerable quantities, although the cellulose content is 20 per cent. It is, however, necessary to get rid of the resin, turpen-

tine and etheric oils, which appear in analyses as crude fat. The scientific authority who made the analysis in Sweden has discussed the use of the needles in bread making, but the Government announces the creation of a factory for "pine and fir needle fodder" only.

In Germany the encouragement and cultivation of the weeds comfrey and coltsfoot is recommended, and in Hungary stinging nettles were being employed in January last. (*National Food Journal*, 12th June, 1918).

THE Sub-Committee of the Committee on Production and Distribution of Milk, appointed to consider the steps necessary for the control, collection, utilisation and distribution of milk sold wholesale, and the need for establishing new depots and the geographical allocation of such depots, has just issued its Report†. The Sub-Committee was appointed as a result of correspondence between Major Astor, the Chairman, and Lord Rhondda in February and March last respecting the probable shortage of milk during the winter months and the consequent need for rationing or the control of distribution. Evidence was taken from twenty-one witnesses.

Difficulties considered.—Special attention was called to the following difficulties :—

1. The wasteful competition in the collection and handling of milk by superfluous depots or factories situated in the same area.
2. The lack of equal distribution of dairy utensils.
3. The diversion from factories or depots of milk produced in the immediate neighbourhood.
4. The uneconomical diversion of milk from one geographical area to another.
5. The unequal supplies that reach various consuming areas in proportion to requirements.
6. The difficulty in suitably allocating the amounts of milk that are required (a) for the manufacture of milk products, (b) for human consumption.
7. The need for a proper organisation to balance supplies and to convert surplus milk into milk products.
8. The unnecessary amount of transportation that takes place by road and by rail in the collection and wholesale distribution.
9. The unnecessary waste of man-power, horse-power, etc., in retail distribution.
10. The fear that large organisations if uncontrolled will ultimately result in a single buyer in particular districts, which would have a prejudicial effect on production.
11. The fear that large combinations of traders if uncontrolled may result in single sellers in particular districts, and thereby place consumers in the hands of a monopoly to the possible detriment of quality, price, hours of delivery, etc.

* Summaries of the 1st and 2nd Interim Reports of the Committee were published in this *Journal*, July, 1917, p. 450, and January, 1918, p. 1138.

† (Cd. 9095), 1918.

12. The need for encouraging the production of cleaner and better milk, thereby (a) making a more wholesome supply and (b) preventing waste.
13. The damage to and loss of milk caused by (a) delays and unhygienic conditions on railways, (b) insufficient treatment prior to transit, such as lack of cooling, (c) unsatisfactory size and type of churn in common use, (d) churns not being locked or sealed throughout transit.
14. The fixing of a uniform maximum price removes incentive to the production of milk of high hygienic quality.

Scheme for Control of Milk Distribution in Great Britain.—The Sub-Committee recommends the following scheme for the control of the wholesale distribution of milk in Great Britain. All the Clauses in this scheme were agreed to without division with the exception of Clause 8. There was a lengthy discussion in regard to Clause 8, which subsequently led to a division, 10 members voting in its favour and five members against it.*

1. The objects to be aimed at are the maintenance of the milk supply, the economical handling of milk, its equitable distribution, and the full utilisation of surplus supplies for manufacturing purposes.

2. For the purposes of controlling the distribution of milk Great Britain should be divided into suitable areas.

3. Milk Superintendents should be appointed in each area to take charge of the local distribution of milk and to act under the instructions of the Central Authority in London, with a separate Advisory Committee for Scotland, meeting in Edinburgh, and under the Central Authority in London. They should have access to the statistics and information in the Live Stock Commissioner's possession.

4. A National Milk Clearing House should be set up in London which should control the wholesale milk trade of the country, and employ persons, firms or societies, who are licensed to deal in milk by wholesale as authorised wholesale milk agents, as far as is necessary.

5. The Clearing House should take over existing contracts between wholesalers and producers, but would interfere as little as possible with direct contracts between producers and retailers. Such contracts would, however, be subject to the supervision and the approval of the Milk Superintendent for the area in which the retailer may be situated.

6. All milk churns in the possession of wholesale dealers, other than retail delivery churns, would be taken over and become the property of the Clearing House.

* The Committee on Production and Distribution of Milk, on receiving the Report of its Sub-Committee, resolved that on the evidence before them they were not prepared to agree to the desirability of purchases recommended in paragraph 8.

They believed that before coming to any decision as to the desirability of such steps, more evidence is required both with regard to the financial terms and to the practical needs and effects of purchasing the entire wholesale milk trade of the country; at the same time, however, they recommended that immediate steps should be taken to determine the basis on which the interests concerned could be acquired should this be deemed advisable at any time by the Government.

7. Manufacturers whose primary business is the manufacture of milk products would be authorised to act as wholesale agents of the Clearing House, and would be required to manufacture dried milk, cheese or other products on account of and in accordance with the instructions of the Clearing House.

8. In the organisation of the wholesale trade during the War, the power of wholesale traders may be strengthened or in some cases disorganised for the period after the War. It is, therefore, recommended that in constituting traders' agents of the Ministry of Food, the Government should at once obtain an option to purchase the businesses of such traders at a fair valuation to be arrived at by negotiation or by arbitration as experience may show the ultimate necessity of the State becoming the sole wholesaler of milk, a development which this Committee considers to be desirable.

9. It should be the policy of the Clearing House to encourage producers to form themselves into co-operative associations for the purpose of improving the conditions of milk production and for the manufacture of cheese.

10. It is recognised that milk should be produced and supplied under improved conditions so that it may be more clean and wholesome when it reaches the consumer. Any improvements that can be effected, by grading or otherwise, should be made in such a way as to anticipate the lines of future requirements.

The Sub-Committee express the opinion that the most suitable locations for the establishment of new milk depots cannot be properly determined in the absence of knowledge that can only be obtained by the exercise of full control over the wholesale trade.

The Report is signed on behalf of the Committee by Mr. Wilfred Buckley, *Chairman*.

THE following Notice was issued on 2nd July, 1918, by the Food Production Department of the Board :—

County Marketing Schemes. The County Marketing Schemes which are being set up on the initiative of the Food Production Department appear to be making very satisfactory progress.

The aim is primarily the organised marketing of surplus fruit and vegetables grown by small cultivators. Last year a certain amount of assistance was given to such cultivators by the Department acting in association with the Agricultural Organisation Society; but only in four counties were there schemes in operation on a comprehensive scale. These counties were Worcestershire, Warwickshire, Carnarvon, and Shropshire.

During the past few months schemes have been taken up in a number of other counties, notably East Sussex, West Kent, Notts, Surrey, Pembroke, and Essex, and at the present time there are seventeen counties where, through Marketing Executive Committees formed by the Horticultural Sub-Committees, organisations have been created for the systematic collection and distribution of surplus produce. In most cases the scheme also provides for the preservation by canning, bottling, drying, etc., of perishable fruit and vegetables to be placed on the market at seasons of the year when fresh supplies are scarce.

In addition to these 17 counties, 14 other counties are prepared to register societies, 7 have made arrangements for marketing, but not as yet by registered societies, 4 have arranged for local markets, 4 others are considering preliminary organisation or deciding to join other counties on a federated scheme. There are 46 counties in England and Wales where systematised marketing is in full swing.

In the departmental suggestions for organisation, liberal allowance is made for the varying conditions existing in the different counties, all of which have to be taken into consideration in establishing suitable local depots. This elasticity of arrangement is appreciated and has been found to work excellently. For instance, in Bucks, Kent, Middlesex and parts of Sussex, the County Organisation consists chiefly of the establishment of stalls in the country markets and the bringing to these stalls of surpluses from the surrounding districts. This admittedly primitive method of handling a somewhat complex problem has proved extremely successful in a number of districts, notably East Grinstead, Chobham (Surrey), and Llanfairfechan.

In North Wales a federation of 6 counties has been arranged, which includes Anglesey, Denbigh, Flint, Carnarvon, Merioneth, and Montgomeryshire, with a Central Marketing Depot at Llandudno and sub-depots in each of the counties federated.

It is hoped that a very important part in the establishment of village depots will be played by women's institutes and similar bodies, which are expected to co-operate in the assembling and despatching of local surplus to the markets. Apart from the patriotic point of view, these schemes have a distinctly advantageous business side, as growers, large and small, market salesmen, small holders, farmers, allotment-holders and gardeners' societies have been called into conference with railway representatives upon the subject. Every county scheme has been started on co-operative lines wherever possible. The value of the shares having been made so low, in order to come within reach of the smallest holder, accounts for the readiness with which capital has been raised in many counties, and offers splendid evidence of local feeling on the matter.

The Progress of Recruiting.—In the four weeks ending 7th June, 3,252 women were added to the Land Army—an advance of 324 on the figures of the previous four weeks. Since the recruiting campaign started at the end of March, 28,393 recruits have enrolled in the Land Army, and just over 25 per cent. of these have been finally selected.

Women's Work on the Land.

The demand for field workers continues, and a growing supply is now available from the gang hostels. The demand for skilled milkers is also increasing. Reports from the various counties show that the need of village forewomen is great.

Women Flax Pullers—Two thousand women are being sent by the Women's National Land Service Corps to Somerset and Northamptonshire to pull flax, and a gang of 200 school girls from the secondary schools in Yorkshire will work in that county and be housed in the gang hostel at Ousefleet. Arrangements have been made whereby Irish women are interviewed by a Ministry of Labour Selection Committee in Ireland and imported into England for agricultural work. These women join the Land Army in the usual way, and when they

reach England are treated in all respects as ordinary recruits. Those enrolling at the present time are being sent direct to Ousefleet to work in connection with the flax harvest.

Girl Students Help Farmers.—Four seasonal gangs of part-time women have been organised in Oxfordshire, where last year the village women are reported to have saved the root crop in many districts from serious damage by weeds. The Business Girls' Gang around Oxford is working well, and it is hoped to establish a club in the city where the business girls who are assisting the farmers in their leisure may meet regularly. Meanwhile, the girl students at Culham Training College—the National Training College for School Mistresses—have undertaken to work on local farms in the afternoons, the head mistress having promised to give extra leave for this purpose. Twelve of the students were recently engaged hoeing land near Oxford.

Women Thatchers.—A most satisfactory report has been received by the Food Production Department as to the competitions recently held among the women and girls who have been taught thatching this year in Cornwall and Devon. "These 16 students," says the Cornish report, "should be of great service to the county." Other counties may be encouraged by the successful results in Cornwall and Devon to institute similar classes with a view to the coming harvest.

The Growth of Allotments.—Recently the Food Production Department asked the local authorities of England and Wales to make a return showing the total number of allotments prior

Notes on Allotments. to and since the outbreak of war. From the actual figures received, and other inquiries of the Department (concerning the increase of privately-owned allotments, including those provided by railway companies), it is estimated that there are now in this country upwards of 1,400,000 allotments. The pre-war figure was about 570,000 allotments and the number laid out since the commencement of war is approximately 830,000.

Few people realise the extraordinary increase in the number of allotments during the past three-and-a-half years. The following figures should give an approximate idea of the enormous expansion of the allotment movement. Returns obtained from 69 of the 81 county boroughs in England and Wales show that there were under 59,000 pre-war allotments in these areas; whereas at present there are over 222,000 allotments, representing an increase of about 280 per cent. 132 town councils reported just under 42,000 pre-war allotments; now there are nearly 97,000 allotments in their areas—an increase of upwards of 130 per cent. In 233 urban districts there were 42,000 pre-war allotments as compared with over 100,000 allotments now in cultivation—the latter figure representing an increase of about 140 per cent.

In December last the Food Production Department appointed certain inspectors to facilitate the obtaining of land by would-be allotment holders and generally to assist the progress of the allotment movement. In six months these inspectors visited over 400 local authorities and consulted with them as to the acquisition of land for allotments. As a result 8,550 additional acres have been laid out by local authorities, providing 127,000 additional allotments. Several thousand allotment plots have also been provided by private owners as the result of negotiations with the departmental inspectors. As an example of the useful

work done by the Food Production Department's officers, the case of a single large local authority may be quoted. In the first instance this authority proposed to provide only $16\frac{1}{2}$ acres of land this year for the purpose of allotments. Arising out of the representations of the departmental inspectors, addition after addition was made to the proposed area; and in the end the authority actually provided 249 acres, giving 7,470 allotments.

The grand total of allotments in England and Wales at present covers an area of about 200,000 acres. Taking this figure—and estimating that 50 per cent. of each allotment is planted with potatoes (a conservative estimate)—we have 100,000 acres of potatoes on our allotments. If these produce an average of 7 tons per acre (a moderate assumption for garden and allotment potato crops) this means that the allotment holders of England and Wales will grow this year 700,000 tons of the most essential war-time crop practically on the spot where this crop is to be consumed.

Next Year's Allotments.—Quite a number of local authorities are looking ahead and arranging for allotments to be laid out for cultivation next year. Amongst these are the local councils of Thrapston (Northants), which is arranging for $4\frac{3}{4}$ acres; Handsworth (West Riding of Yorkshire), 6 acres; and Shipley, 3 acres.

Allotments at Alexandra Park.—Fifteen acres of land at Wood Green are being laid out to provide 225 war-time allotments. This land adjoins the race track at Alexandra Park and is the property of the Alexandra Park Race Course Syndicate. The Syndicate has agreed to surrender the land for spade cultivation, and the Cadet Corps of the Women's Land Army will undertake the work after this year's hay crop has been harvested.

A Famous School-town and its Allotments.—Oundle, the little north Northamptonshire town where there is a famous school, is among the places that have done exceptionally well in the matter of allotments. Two hundred and fifty-seven householders are cultivating an aggregate of $33\frac{1}{2}$ acres of land. In addition the boys at the school have $8\frac{1}{2}$ acres of allotments, whilst even the inmates of the workhouse are doing their bit by growing foodstuffs on $2\frac{1}{2}$ acres. Moreover, upwards of 50 per cent. of the 580 houses in the town have gardens attached to them, and these on the whole are being judiciously cultivated.

The Garden Fire.—The smother fire is a useful institution, which should be seen in more gardens and allotments. A well-made fire will smoulder for a considerable time, and on it all garden refuse may be deposited. Cabbage stumps, decayed leaves, weeds, finished and exhausted plants, potato haulms, etc., can by this means be thoroughly destroyed, and it is the best receptacle for all diseased and insect-infested plants and leaves. The ashes from such a fire should be carefully saved, forming as they do a very valuable fertiliser to be scattered over the soil and forked or dug in.

Rotation of Crops.—Many hold the belief that the potato must or should be put into fresh ground each season, but this is not the case. Provided the soil is deeply worked and suitable enrichment is added, potatoes can be grown on the same site for an indefinite number of years. Change of seed should be obtained, however, from another district. The Brassicas differ from the potato inasmuch as for these one season at least, and two for preference, should elapse before a return to the same spot. This arrangement, unfortunately, is not always

possible in a small garden, and here deep trenching and the judicious use of lime must be resorted to.

Another subject which has no objection to remaining on the same site for a number of years is the onion, provided the ground is well enriched. Peas should always have a fresh place selected for them, wherever possible, each year, failing which deep trenching must be done.

Some of the other vegetables thrive well on the same site for a number of years, and of these the best known and most useful are leeks, shallots, artichokes (both globe and Jerusalem), horseradish and carrots.

OFFICIAL NOTICES AND CIRCULARS.

N.B.—The Orders which may be mentioned in this section of the JOURNAL may usually be obtained at the price of 1d. each from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, and 28, Abingdon Street, London, S.W. 1; 37, Peter Street, Manchester; and 1, St. Andrew's Crescent, Cardiff.

THE following Circular Letter (No. C. L. 54/C. 1), dated 24th May, 1918, was addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Programme of the Food Production Campaign, 1918-19.

SIR,—1.—The Department have had under consideration the form of organisation which should be adopted for carrying out the Food Production Campaign next season. During

the past 15 months the organisation had to be built up piecemeal in order to cope with the various duties which have from time to time been entrusted to the Committees. The result has been that there is lack of co-ordination between some branches of the work, and a divided control in certain matters which ought to be remedied.

2. It has, therefore, been decided to place in the hands of the Committees more complete control of the local organisation of the Tractor Scheme, so as to enable it to be worked jointly with the Horse Scheme, and also to ask the Committees to make certain changes in regard to their own organisation and staff, with the object of securing better co-ordination of the work generally as well as a greater measure of delegation to the Districts.

3. The detailed proposals with regard to the co-ordination of the Tractor and Horse Schemes are set out in the Memorandum (Enclosure No. 1) which accompanies this letter, but the general scheme of organisation which the Department propose is as follows :—

4. **County Organisation.**—*Chief Executive Officer.*—In the first place the Department consider that the time has come when each Agricultural Executive Committee should have one principal official who is in general charge of the whole of their work and who should be responsible to them for seeing that the work of the different branches is properly co-ordinated, and that the policy of the Department and of the Committee is carried into effect. This official should be called the Chief Executive Officer, and, in view of the importance of his duties, the Department are prepared to authorise payment up to £500 a year if necessary to secure the services of a suitable man. In some cases one of the existing officials may be fitted for this post, but this will not always be the case, and the Committees must not hesitate if necessary to select a man

from outside. Any appointments to this post will have to be submitted to and receive the approval of the Department. The Chief Executive Officer should be responsible to the Agricultural Executive Committee for the whole of the work carried out in the county except (1) the actual correspondence and minutes of the Committee for which the Secretary would be responsible, and (2) the financial business which would be undertaken by the Finance Officer. The duties of the latter officer are becoming increasingly important, and the Department are prepared to consider proposals for the payment of an adequate salary for the post. In those counties where the County Accountant has been good enough to undertake the charge of the Committee's finance an allowance might be made to him or to some member of his staff.

5. *Sub-Committees.*—It is proposed that in all counties the principal work of the Agricultural Executive Committees should be undertaken by five main sub-committees, as follows :—

(1) Cultivation Committee, (2) Labour Committee, (3) Supplies Committee, (4) Horticultural Committee, (5) Finance Committee.

6. The work of the Labour, Supplies, Horticultural and Finance Committees will remain as heretofore. The Cultivation Committee, however, should be a new Committee charged, not only with the duties of controlling the Horse and Tractor Schemes, but also with the survey, the recommendation of cultivation orders and the general supervision of farming in the county. In those matters where action under the Defence of the Realm Regulations is required, the recommendations of the Cultivation Committee should be submitted for the approval of the Executive Committee. The Cultivation Committee will, therefore, take over all the duties of the Machinery Committee, which will cease to exist as such, such part of the duties of the Labour Committee as related to the administration of the Horse Scheme, and the duties the Survey or other Committee which has hitherto been responsible for the survey and the issue of cultivation orders.

7. In those counties in which steam-tackle is employed, a representative of the steam-tackle industry should be co-opted on to the Cultivation Committee so that he may attend all meetings at which matters affecting this industry are under consideration.

8. The Threshing Committee which has been constituted in most counties will act as a Sub-Committee of the Cultivation Committee.

9. *Staff.*—The Chief Executive Officer as stated above will be in charge of the staff, and he should attend the meetings of the Agricultural Executive Committee and of the principal Sub-Committees, and also supervise the outdoor work in the country. He will also be responsible to the Department for seeing that stock-records are efficiently kept in respect of all Government property placed at the disposal of the Committee. Under him there should be the following county officials each responsible for one branch of the work :—

(1) The Tractor Representative, who would undertake the general control of the tractors in the county and the supervision of the engineer contractors.

(2) The Horse Officer, who would undertake the general control of the horses and horse-drawn implements in the county, together with the supervision and care of the horses and the supply of forage.

(3) The Deputy Executive Officer, who would be the principal assistant of the Chief Executive Officer in regard to the survey, the

supervision and inspection of farms and the issue of cultivation notices. For this post the present Machinery Officers might in many counties be suitable.

(4) The Labour Officer, who would undertake the control and distribution of the soldier, prisoner and war agricultural volunteer labour placed at the disposal of the Committee, and the work in connection with the recruiting of labour from the land, including the issue of vouchers.

10. In most counties the Secretary of the Agricultural Executive Committee will, it is hoped, be able to act as Secretary to the Cultivation Committee also, but in cases where the Agricultural Executive Committee consider that this course would not be practicable the Department will be prepared to consider a proposal to appoint a special officer for this post at a salary not exceeding £200 a year.

11. The appointment of Tractor Representatives and Horse Officers will be subject to the approval of the Department, which will require to be informed of the qualifications of the candidates selected, and the amount of the salary proposed. For the present the post will be filled by the existing occupants, and, in view of the experience which they have acquired in carrying out their duties, the Director-General will not be prepared to sanction their removal within a period of six months from 1st July next unless the specific approval of the Department is obtained in each case.

12. **District Organisation.**—As the work of the Agricultural Executive Committees has developed it has become apparent that there must be a greater degree of decentralisation to District Committees. Some of the county officers have had far more work than they could do efficiently owing to the fact that the area they had to cover was far too large. It is, therefore, proposed that the local organisation should be brought down to the areas covered by the existing District Committees, and that there should be one paid whole-time official in each district responsible for all branches of the work of the Executive Committee. The proposed officer, who should be called the District Executive Officer, should be appointed by the Agricultural Executive Committee, subject to the approval of the Department, and might be paid a salary not exceeding £250 per annum.

13. The District Executive Officer would act generally as the agent of the Executive Committee for all purposes in the district, and his work would include any necessary inspections as well as the duty of controlling the work of the tractors and horses allocated to his district, supervising the labour employed and making contracts for cultivation. He should be responsible for the various branches of his work to the Chief Executive Officer of the county, the Tractor Representative, or the Horse Officer as the case may be. He should also work in close touch with the District Advisory Committee, but as it is essential that he should constantly be moving about his district, he must not be burdened with clerical work. It should be arranged, therefore, that all correspondence, the keeping of records and the minutes, etc., of the District Advisory Committees should be undertaken by the Secretaries of those Committees, and the Department are prepared to consider proposals for an increase in their remuneration where necessary. In many cases it should be possible to arrange that the services of the Supplies Clerks under the Tractor Scheme should be made available to assist in this clerical work.

14. *Commencement of Scheme.*—It is proposed that the scheme of re-organisation outlined above shall come into force on the 1st July, and the Department ask that in the first instance, and not later than the 15th June, a detailed scheme may be submitted to them, showing the manner in which it is proposed to apply to the county the principles embodied in this letter and the appointments which it is proposed to make.

15. A statement (Enclosure, No. 2) is enclosed * showing the staff which should be provided in each county, together with a list of the posts which should be abolished.

I am, etc.,

(Signed) A. LEE,

Director-General.

ENCLOSURE.

1. The main object which it is necessary to keep in view in co-ordinating the working of the Tractor and Horse Schemes is to make such arrangements as will facilitate :—

(a) The allocation of tractors or horses to the work for which they are best suited.

(b) The interchange of implements between the Tractor and Horse Schemes.

(c) The making of one contract with farmers for work to be done whether by tractors or horses.

2. In almost every county at the present time the local working of the two schemes is being carried out by entirely separate staffs, and the officers concerned with the Tractor Scheme are appointed directly by the Department. In future, however, the single staff provided for in the revised scheme of county organisation, all members of which will be under the control of the Agricultural Executive Committee, will be responsible for both Schemes.

3. The local area to be adopted for the purpose of the Schemes should be the area covered by the existing District Committee, and the working arrangements of both tractors and horses in it should be undertaken by the District Executive Officer, whose appointment and duties are dealt with in the covering letter. The present functions of the Tractor Supervisor and local Horse Officer will accordingly be transferred to him, and also the local duties of the Machinery Officer, and these three posts will be abolished. Owing to the new districts being in practically every case smaller than the area at present used for units of tractors, it will usually be possible for the whole of this work to be undertaken by the District Executive Officer. In special cases, however, where the amount of work necessitates such a course, an assistant could be appointed to the District Executive Officer, but this should not be necessary in districts of the average size (say 30 to 50 parishes).

4. The Department have at present for every unit of tractors a store for spare parts and fuel, and an office with a Supplies Clerk, who is a whole-time officer. It will be the duty of the District Executive Officer to arrange, wherever possible, for the Supplies Clerk to assist the Secretary of the District Committee with all the clerical work which has to be undertaken in the district, such as recording cultivation

* Not here printed.

orders and contracts, transmitting the acknowledgment of work carried out to the Finance Officer, keeping a register of the implements allocated to the district.

5. The District Executive Officer will also be responsible for making local arrangements for taking out the supplies of fuel, harness, fodder, etc., which is now generally done personally by the Tractor Supervisors or the Horse Officers. The cars used hitherto by Tractor Supervisors should be handed over for the use of the District Executive Officers.

6. In order that the Department may be in a position to supply Parliament and the Government with full information as to the working of the Horse and Tractor Schemes, and also maintain supervision over the consumption of fuel and the general cost of the Schemes, it is essential that any returns shall be furnished that the Department require. Pending further directions on this point the Cultivation Committee will be responsible for seeing that the weekly and other returns now supplied by Tractor Representatives and Supervisors continue to be furnished regularly and without delay. The Department must also continue to send its expert officers to inspect and report upon the condition and working of the Government horses, machinery and implements in the different counties. By this means it is hoped to place at the disposal of the Cultivation Committee and its officers special technical knowledge which will assist them in operating the machinery and implements to the best national advantage.

7. The Department will issue a further communication with regard to the transfer to Executive Committees of the responsibility for the local expenditure under the Tractor Scheme, which hitherto has been undertaken by the Department itself.

THE following Memorandum (No. C. L. 36/H), dated 5th July, 1918, has been addressed to Horticultural Sub-Committees by the Food Production Department of the Board :—

Scheme for Rabbit Breeding and Keeping.* At the instance of the Food Production Department, some of the leading rabbit-breeders and keepers throughout the country have formed an association registered under the title of the National Utility Rabbit Association. The Association is established in premises at the Model Farm, Neasden, London, N.W., where it has formed a Central Breeding Station and Stud Exchange, stocked with rabbits or the best breeds.

1. **Objects of the National Utility Rabbit Association.**—The primary object of the Association is to build up as quickly as possible a large stock of the best utility rabbits. The rabbits from the Central Station will be sold at the lowest possible prices to district breeding-stations to be set up in different parts of the country. The district stations will in turn supply, at lowest possible prices, breeding-stock to smaller stations in villages and towns. The ultimate object of the Association is to provide, through these stations, rabbits for keeping by private persons in town and country and thereby to increase largely during the next twelve months the supply of rabbits for food purposes.

*See also this *Journal*, June, 1916, p. 340.

Each district breeding-station will be a 100-doe centre, and will be kept by a person who already has 50 rabbits and who is willing to keep at least 100 breeding does. The smaller breeding-stations will be 20-doe centres and will be kept by persons who undertake to maintain a stock of at least 20 breeding does.

The Department understand that already 200 persons have expressed their willingness to establish a 100-doe centre.

2. Advantages of Membership of, and Affiliation to, the Association :—

- (i.) Purchase of rabbits through the Association at lowest possible prices.
- (ii.) Advice in procuring accessories and foodstuffs necessary for the keeping of rabbits.
- (iii.) A share in the work of the Association in promoting work of national utility.
- (iv.) Expert advice on all matters relating to the keeping of rabbits.

3. County Organisation.—It is suggested that the County Horticultural Sub-Committee should take the initiative in organising the county scheme, and the following proposals as to method are put forward by the Department with the object of assisting the Committee and ensuring a measure of uniformity in each county :—

District Breeding Stations.—At the request of the Department the National Utility Rabbit Association is preparing a list of persons in each county prepared to establish forthwith district breeding-stations (100-doe centres).

The duties of the Superintendent of the 100-doe centre will be :—

- (a) To maintain not less than 100 breeding does and the necessary number of bucks.
- (b) To sell at agreed prices to the Central Breeding Station or any other breeding centre affiliated to the Association a portion of his stock suitable for breeding.

In the case of pedigree stock the proportion available must vary from time to time, and the exact proportion to be disposed of must be a matter of conference between the Secretary of the Association and the owner of the station.

- (c) To maintain the stud bucks supplied to him from the Central Breeding Station for the use of the breeding-centres in his district.
- (d) Generally to assist the rabbit clubs in his district.
- (e) Each centre shall be self supporting.

Generally speaking it will be found that one district breeding-station will supply two or three Rural Districts, but that one station or even more will be required in each Urban District.

The Horticultural Sub-Committee will probably desire to delegate the organisation of rabbit-keeping in the neighbourhood of district breeding stations to its local (District or other) Committee. Committees which adopt this course will probably find it convenient to elect the keeper of the District station as a member of their Committee.

The Department consider that the best way in which the Horticultural Sub-Committee can assist the Association will be to secure as soon as possible, through their District and Village Committees, the formation of rabbit clubs in every village and small town in the county.

4. Rabbit Clubs.—Wherever a number of persons desire to keep rabbits co-operatively, they should form a rabbit club and either establish a 20-doe centre or become associated with such a centre already established in their immediate neighbourhood. All these clubs should affiliate with the National Utility Rabbit Association. The fee for such affiliation for a club of 20 members or any fraction thereof is 5s. per annum. Clubs of more than 20 members shall pay a fee of 5s. per annum for every 20 members or part thereof, *i.e.*, a club of 55 members will pay a fee of 15s. per annum. In addition, clubs may purchase shares at the rate of £1 per share. The affiliation fee carries with it the right to enjoy the privileges attaching to affiliation with the Association which are set out in paragraph 2.

Any person desirous of becoming a Vice-President of the Association may do so on payment of £10 10s. or a Life member on payment of £5 5s. Anyone joining the Association as a member, Vice-President or Life member will be entitled to purchase stock for breeding, together with such material as he may require, direct from the Central Breeding Station.

Some time must elapse before keepers of 20-doe centres are in a position to provide rabbits required for keeping by members of their club, but during this period, and subsequently when necessary, they will be entitled to apply to the 100-doe centre or the Central Breeding Station for a fair allocation of stock for this purpose. Similarly, a 100-doe centre short of stock will be supplied direct from the Central Breeding Station in London, which will supply all the stock that may be required. It is important that all rabbit clubs, both those already in existence and those to be formed, should affiliate with the National Utility Rabbit Association so that rabbit-breeding may be developed on national lines.

5. Rabbit Club Rules.—Each rabbit club should be properly constituted with a Secretary and Treasurer and should have properly drawn-up rules. A draft set of rules is enclosed herewith* and copies will be sent from the Department for distribution to the subsidiary organisations of the Horticultural Sub-Committee. These are model rules, and are only meant to serve as a guide. New clubs may prefer to alter them to suit local requirements, but uniformity is very desirable.

6. Prices of Rabbits.—The National Utility Rabbit Association has been registered under the Industrial and Provident Societies Acts, 1893 to 1913, and trading transactions which it carries on are undertaken in the interests of members and affiliated societies, and not with the object of making profit. The policy of the Association with regard to prices is to bring the utility rabbit within the reach of every cottager and allotment holder, but it must be remembered that the prices of the finest pedigree stock, as distinguished from the utility stock, must always be higher. The Association will fix a list of prices of utility rabbits to be supplied from the Central Breeding Station to the 100-doe centres; these prices will also rule for utility rabbits supplied from the 100-doe centres to the 20-doe centres.

7. General information.—All associations should apply to the Food Production Department for pamphlets and leaflets on rabbit-keeping and breeding.

* Not here printed.

THE following Memorandum (No. C. L. 103/12), dated 5th July, 1918, has been addressed to Agricultural Executive Committees by the

Food Production Department of the Board :—

Labour for the Harvest. The sources of additional labour for harvest work are as follows :—

Prisoners of War.—All Committees have already been informed of the number of prisoners who can be placed temporarily at their disposal in migratory gangs, to work in the harvest, in addition to the prisoners of war already on agricultural work in the county.

Convalescent Soldiers.—An Army Council Instruction will be issued in the course of a few days, authorising the employment of suitable convalescent soldiers on harvest work on condition that they return to hospital each night, or once every three days for medical examination. Copies of this Instruction will be sent to all Committees, and also a list of the hospitals in their area. On receipt of this list Committees should communicate with the Commandant of the Hospital, with a view to ascertaining how many men are likely to be available from each hospital. It will be advisable for Committees to appoint local representatives in each case to organise and distribute the men available.

A small number of soldiers from Command Depots will also be available for harvest work on a month's agricultural furlough.

Public and Secondary Schoolboys.—Many thousands of these boys are available, and doubtless all Committees desiring their services have already arranged with the Ministry of National Service for the formation of camps in districts where much extra harvest labour will be required.

Women.—A large number of women are available, and Committees should arrange for their distribution in consultation with the Women's War Agricultural Committee for the county.

Royal Air Force.—The Air Board has given instructions that men are to be encouraged to volunteer for harvest work in the neighbourhood of their camps when they can be spared from their ordinary duties. Commandants of Royal Air Force stations, aerodromes, etc., should be asked how many men are likely to be available.

War Agricultural Volunteers.—Every effort should be made to enrol every suitable man under the War Agricultural Volunteer scheme. The enrolment of these men will make additional men available for harvest, but, of course, no man who is not suitable to be employed as a permanent farm worker can be enrolled.

Local Authority Employees and Police.—A copy of a Circular Letter issued by the Ministry of National Service to all county clerks, town clerks, and chief constables, is enclosed* for the information of Agricultural Executive Committees. Committees will observe that special facilities are granted in order that Local Authority employees and policemen may undertake harvest work, and they should communicate with the local bodies in their area with a view to obtaining the assistance of as many of these men as can possibly be spared.

Part-Time Labour.—Steps must be taken to organise all part-time labour that is available. In many districts there are already Part-time Committees, under the Ministry of National Service, who are assisting with farm work. In other districts Committees might appoint a local representative to organise all part-time labour and place it with farmers. In some counties it has already been arranged for the

* Not here printed.

whole of the roadmen to be made available, and quarry owners in some cases are releasing a large number of men. Employers of labour in the county should be approached with a view to giving assistance to farmers in the neighbourhood during the busy time of the harvest.

After ascertaining the supplies of labour that will be forthcoming from the above sources, and consulting the district committees as to the amount of labour that will be required to get in the harvest, Agricultural Executive Committees should inform the Department if they are of opinion that it will be essential to provide additional whole-time labour. The number of additional men who will be wanted should be stated, and the date on which they will be required. The Department are, of course, unable to guarantee that these additional numbers can be provided.

THE following Appeal was addressed to the women of Great Britain by the Prime Minister on 26th June :—

“ The fields are ripening for the sickle ;
 the toil of the winter and the spring is
 earning its reward. This is no ordinary
 harvest ; in it is centred the hope and
 the faith of our soldiers that their own
 heroic struggle will not be in vain.

In the days before the War the whole world was our granary. Now, not only are thousands of men fighting instead of tilling our own fields, but the German submarines are trying to starve us by sinking the ships which used to carry to our shores the abundant harvests of other lands.

Women have already served the Allies by their splendid work upon the farms, but the Army in France has asked for still more men from the land to come and help their brothers in the desperate battle for Freedom. These men must go ; women will be first to say it. But the harvest is in danger for want of the work these very men would have done.

Once again, therefore, as often before, I appeal to women to come forward and help. They have never failed their country yet ; they will not fail her at this grave hour. There is not a moment to lose.

Every woman who has the great gifts of youth and strength, if not already devoting these to essential work for her country, should resolve to do so to-day. If she lives in a village let her go out and work in the fields from her home. If she can give her whole time, let her join the ranks of the Land Army. From the nearest Employment Exchange she can learn all about the conditions of service.

I have watched with deep interest and admiration the splendid work already done. Never have British women and girls shown more capacity or more pluck. And just as the soldiers have asked for thousands more men to come and help

them to win the War, so do these brave women in the villages and in the Land Army call to other women to come and help them save the harvest.

I know this appeal will be heard. Ask the women who have already shown the way, what they feel; they will declare that work in the fair fields of our green Island is a privilege as well as a duty."

(Signed) D. LLOYD GEORGE.

THE following information has been issued by the Ministry of National Service :—

General.—War Agricultural Volunteers are men who enter into an agreement with the Minister of National Service to undertake agricultural work to which they may be assigned by the Minister during the War for a period not exceeding 12 months in all.

**War
Agricultural
Volunteers.**

[No man will be enrolled as a War Agricultural Volunteer until he has actually been accepted by an employer as suitable for an actual vacancy; and if the vacancy has been "approved" by the relative Agricultural Executive Committee. Vacancies for "seasonal workers" will not be so approved.

Men will be enrolled as War Agricultural Volunteers either through the agency of an Employment Exchange or through the Agricultural Executive Committees. They will be enrolled either for general work, *i.e.*, for work anywhere in England or Wales, or for local work, *i.e.*, work within daily reach of the Volunteer's home. The terms of the undertaking signed by War Agricultural Volunteers are set out respectively on the next page. The undertaking in each case entitles a Volunteer to the current rate of wages for the job on which he will be employed, and also to certain allowances in respect of travelling or subsistence, and, further, to certain "out-of-work" allowances. *The allowances (except out-of-work allowances) will be paid to the Volunteer by the Agricultural Executive Committee and recovered by them from the Ministry of National Service. "Out-of-work" allowances will not be payable by the Committee, but by the Ministry of National Service through the Employment Exchanges.*

If any Volunteer who is directed by the Ministry to work with an employer presents himself for work and is not immediately started, it will be necessary for the employer to pay him for any time lost. Such payments are not recoverable from the Ministry.

Position with regard to Military Service.—No man who has not attained the age of 45 at the date of his application for enrolment will be enrolled as a War Agricultural Volunteer unless he proves that he is in Medical Categories B3 or C3 or in Grade 3. Any man, however, who has attained the age of 45 on that date will be eligible for enrolment.

Whilst enrolment as a War Agricultural Volunteer does not in itself afford protection from Military Service, the Ministry of National Service have arranged *that so long as a man continues to be engaged in employment as a War Agricultural Volunteer he will, for the present, on application, be protected from liability to be called up for Military Service :—*

- (a) Without regard to his medical category if he had attained the age of 45 at the date of his application for enrolment ;

- (b) Provided that he proves to be in Medical Categories B3 or C3 or in Grade 3 if he had not attained the age of 45 at the date of his application for enrolment.

War Agricultural Volunteers will be given, upon enrolment, a form upon which they can claim the protection referred to above. This form will be taken by the Volunteer to his employer and, after being countersigned by the employer, should be sent or handed to the Assistant Director of National Service of the district in which the man is employed.

Note.—Further information may be obtained on application to County Agricultural Executive Committees, at offices of County Councils, or from the nearest Employment Exchange.

TERMS OF AGREEMENT.

WAR AGRICULTURAL VOLUNTEERS.

I hereby agree with the Minister of National Service to undertake agricultural work :—

- (*) (a) Generally, upon such farms as may be named by him ;
 (*) (b) Locally, upon such farms as may be named by him ;
 and to remain at such work upon the conditions set out on this form during the War for as long as required by the Minister not exceeding twelve months in all.

(a) That is, anywhere in England or Wales.

(b) That is, within daily reach of his home.

(*) Strike out the line which does *not* apply.

The conditions are as follows :—

1. The rate of my wages, while I am engaged upon such work, shall be the rate current for the job upon which I shall be employed.

2. I shall receive over and above my wages, the following allowances :—

(i.) *Travelling* :—

(a) If the farm is at a distance beyond that which, in the opinion of the Minister, I can reasonably travel daily from my home, a free railway warrant at the commencement and completion of the work which I am directed to take up ; or

(b) If the farm is within daily travelling distance from my home, the daily cost, if any, of a workman's return ticket by railway.

(ii.) *Subsistence* :—

If the work is at a distance beyond that which, in the opinion of the Minister, I can reasonably travel daily from my home, subsistence allowance, if necessary, whilst I am working at such work at the following rates :—

(a) If married, or if unmarried, and my home is mainly dependent on me, 2s. 6d. per day for seven days per week ;

(b) If unmarried, and my home is partially dependent upon me, 1s. 6d. per day for seven days per week ;

if I show to the satisfaction of the Minister that I have dependents for whose maintenance I am responsible and from whom I am obliged to be separated owing to my being at such work.

3. The allowances which I am to receive under this agreement other than those specified at 2 (i.) (a) above and 4 below, are to be paid to me by the Agricultural Executive Committee.

4. *Out-of-Work Allowances.*—If, after being placed in employment by the Minister of National Service, my employment, owing to no fault of my own, comes to an end during the War, and no further work is available for me, I may be entitled to receive, whilst no work is available for me, an Out-of-Work Allowance at the rate of 3s. 6d. per day (including Sunday), for any remaining portion of a period of six months, which period shall commence on the date on which I am first placed in employment by the Minister of National Service. The first payment of such Out-of-Work Allowance shall be due one week after the commencement of unemployment.

5. I shall be subject to the ordinary working conditions attaching to the employment in which I am directed to work by the Minister.

6. Any question which arises as to the interpretation of the foregoing provisions shall be determined by the Minister of National Service.

Signature

Signed in the presence of

Date 191 ..

THE following Notice was issued on 19th June, 1918, by the Food Production Department of the Board :—

**Scheme for the
Employment of
Prisoners of War
to Assist in the Hay
and Corn Harvests.**

1. In the neighbourhood of agricultural camps, parent camps, etc., prisoners will be available in the ordinary way for employment on harvest work. All prisoners in agricultural camps and at least 50 per cent. of the prisoners employed on land reclamation work should be made available for harvest work, and those surplus to the requirements of the neighbourhood should be sent out in migratory gangs as in paragraph 2. Government Departments employing German prisoners are being approached with a view to as many as possible of the prisoners they employ being released for harvest work. So far as possible such prisoners should be employed in the neighbourhood of their working camps, but any balance will be available for employment in migratory gangs.

Migratory Gangs.—2. Each gang will consist of 10 prisoners and 2 guards and be available to meet the requirements of those districts which are not served by any existing prisoner-of-war working camp. The prisoners for these gangs will be supplied from the sources mentioned in paragraph 1, as well as from prisoners temporarily placed at the disposal of the Agricultural Executive Committee by the War Office for this purpose, and sent direct from parent camps.

3. The Agricultural Executive Committee should report to the Department at once the number of migratory gangs which it expects to provide from agricultural and land reclamation camps, and how many additional prisoners they require for additional gangs during harvest.

4. The Committee must decide where each migratory gang is to be located for harvest work. In this connection it should be noted that :—

- (a) Migratory gangs must not be worked within five miles of the coast without the express sanction of the Area Commandant or in the vicinity of an aerodrome, munition works, or any other important military or naval station.
- (b) Prisoners must not be worked in a neighbourhood served by a schoolboy camp or women's agricultural camp.

5. The Committee will select and secure accommodation for each gang consisting of not more than 12 (10 prisoners and 2 guards) in a lock-up building, centrally situated and suitable for accommodating the whole of the gang at a fixed price of 3*d.* per head per night (to include a sufficient supply of good water). Where such accommodation cannot be secured a suitable site for the erection of one or two tents must be procured at a cost not exceeding 1*d.* per head per night (to include a sufficient supply of good water). Payment for the accommodation at the prices fixed must be made by the Committee out of the monies provided for in paragraph 17. Where gangs greater than 12 are required the local Quartering Committee must be consulted as to their housing.

6. The Commandant of prisoners of war for the area must be notified of the arrangements made for accommodating migratory gangs at least 14 days before the date on which it is desired that the camp should be opened. Any subsequent change in the location of a camp will be a matter of arrangement between the Commandant and the Committee. This will enable prisoners to be moved to a new district at short notice.

7. In arranging the places to which migratory gangs should first be sent in accordance with paragraph 4, the map should be studied with a view to an equitable distribution, bearing in mind the position of existing camps. The Committee should assign a serial number to each migratory gang, and send a list showing the number and place selected for each gang to the Commandant. The serial numbers should be used in all correspondence, records, and accounts.

8. The Military Authorities will supply the necessary tents and stoves, and the prisoners will be provided with palliasses, blankets, mess-tins and cooking utensils.

9. The Committee must appoint a local representative, who should either be a member of the Committee's existing staff or a non-salaried representative for each migratory camp, who will be responsible for allocating the prisoners locally amongst the farmers requiring them for harvest work, or, if such work is delayed or stopped owing to bad weather, for any other work of a useful character. He will also deal with any minor complaints, and if the Committee so desire he will collect on their behalf the sums due for the employment of the prisoners.

10. The following charges for prisoner labour have been fixed:—

- | | |
|--|---|
| (a) Whilst employed on hay harvesting. | 4s. 6d. per day of 10 hours (excluding meal times). |
| (b) Whilst employed on corn or potato harvesting. | 5s. 6d. to 6s. 6d. per day of 10 hours (excluding meal times). |
| (c) Whilst employed on ordinary agricultural work owing to harvest work being stopped in the locality. | The existing rate of pay for prisoners employed on agricultural work in the county, less one halfpenny per hour to meet part of the cost incurred by the farmer in providing the mid-day meal and refreshments. |

When employed on haysel or corn harvest overtime to be charged at 8d. per hour.

The Agricultural Executive Committee will be responsible for the collection of these charges.

In addition each farmer will be required to provide, at his own expense, a suitable mid-day meal for the prisoners he employs. Tea, coffee, cocoa, or milk may be given, but not intoxicants.

No farmer or other person may give money to a prisoner of war, otherwise he will be guilty of a breach of the Defence of the Realm Regulations.

11. Except as stated above rations for the prisoners and guard will be supplied by the Military Authorities.

12. The Guard will keep in duplicate a record showing by whom each prisoner is employed each day, the nature of the work done, hours of overtime worked, etc. One copy of this is to be sent each Saturday to the Commandant, and the other to the local representative of the Agricultural Executive Committee, who will examine it and send it to the Committee with the amounts collected from the employers if the duty of collection has been assigned by the Committee to the local representative.

13. Each gang will be nominally attached to a prisoners of war camp in the county, and the officer in charge will pay periodical visits to see that the prisoners and guards are properly accommodated, and will be responsible for the feeding and general discipline of the gang, payment of guard, etc.

The Agricultural Executive Committee should arrange for a motor conveyance, preferably one of the Ford cars (with van attachment),

to be made available for taking this officer to inspect these migratory camps, as it is important that strict discipline should be maintained.

14. The guard will not be required to undertake agricultural work, but if, with the consent of the Officer Commanding, any such work is undertaken, the rate of pay must be the subject of mutual arrangement between the guard and the employer.

15. Farmers employing prisoners will be responsible for their safe custody from the time of their leaving the camp in the morning until their return at night. Prisoners must be returned and handed over to the guard at night not later than half-an-hour after sunset.

16. The Committee must arrange for the conveyance of the equipment of the prisoners and their guard to and from the nearest station, etc., as well as in connection with any intermediate movements of the camp during the harvest period. The cost of such conveyance must be paid for by the Committee out of the monies provided for in paragraph 17.

17. Lorries and teams in the possession of the Committee should be used for the purpose if in the vicinity.

17. As stated in paragraph 10, the Agricultural Executive Committee will be responsible for the collection of the sums due from employers for the services of migratory gangs. These amounts should be collected each week either by the District Representative responsible for each camp and forwarded by him to the Finance Officer of the Committee, or in such other manner as the Committee may determine.

The Committee must keep a separate account in respect of each prisoner of war command to which gangs are attached, and render an account and pay over monies to the Commandants concerned at the end of each month, *after deducting the following items* :—

- (a) The sums paid for the accommodation of prisoners and guard in accordance with paragraph 5 ; and
- (b) The sum of 1s. in the £ on the full amount received for the prisoners' work.

The amount produced by the latter deduction is intended to meet the costs to which the Committee will be put in connection with the scheme, in addition to the expense of providing accommodation.

18. An account of the receipts and payments on the scheme as a whole should also be included in summary form in the quarterly accounts rendered by the Committee to the Food Production Department, the relative service account being entitled the "Prisoners (Migratory Gangs) Employment Account." The sums retained under paragraph 17 (b) should be transferred periodically to the Committees' Administration Account.

19. The Committee should appoint a representative to be responsible for the supervision of the scheme throughout the county, working in close touch with the Military Authorities.

THE following Notice was issued towards the end of June by the Food Production Department of the Board :—

**Government Tractor
Competitions:
Fine Work by
Wounded Soldiers.**

The awards in the Gordon Selfridge Tractor Prize Competition (open to all Government-owned tractors in England and Wales) have been made this week. Twelve prizes were offered by Mr. Selfridge for competition among Government tractor ploughmen, six 1st prizes of £50 each and six 2nd prizes of £33 each. The first and second prizes

for the best acreage achieved, and the first and second prizes for the lowest fuel consumption, were offered for each of three different periods—one period of three months, one of two months, and one of one month, both the shorter periods being included in the longest period.

It is interesting to note that no fewer than 20 out of the 24 men sharing in the prizes are soldiers.

The Highest Acreage.—The Holland Division of Lincolnshire carries off chief honours in the competition, winning 3 out of the 12 prizes; one first for acreage and one first and one second for low fuel consumption. The first prize for the highest acreage achieved for the 3-months period was won by Titan tractor No. 2736, with the highly creditable score of 354½ acres. The men operating the tractor were both soldiers. Pte. W. Drewett is a native of Hastings (East Sussex), where, previous to the War, he drove a motor-bus. Pte. R. Beard, his mate, is also a Southerner, coming from St. Mary Cray (Kent). In years gone by he had worked as a farm hand; but he had been driving a motor-van for some time when war broke out. During the competition, when light permitted, they worked 98 hours a week. All the ploughing was done with a self-lifting plough. Thus Drewett and Beard were able to take turn and turn about at starting and stopping work early; and, by having their meals at different times, they kept the tractor working continuously during the daylight. Only one serious breakdown occurred; this entailed a delay of five hours for repairs.

The Lowest Fuel Consumption.—The first and second prizes for low fuel consumption in the two-months period were won by two Fordson tractors, both manned by soldiers. The first prize-winner is Tractor No. 70, the consumption of which worked out at 2.13 gal. to the acre. "My mate, Dorsay, used to laugh and say 'we should squeeze the tins,'" said Pte. J. E. Kirkbright, referring to the thoroughness with which they drained every can of fuel.

Kirkbright, who hails from Durham county, was managing a large hosier's shop in Stockton-on-Tees before he donned khaki. Prizes seem to come his way naturally; for he had won two first prizes for window dressing in more peaceful days. His mate, Pte. T. Dorsay, showed great pluck by carrying on when he was really too ill for work. He suffered from an old wound and the after-effects of being gassed; but he made light of his ailments till the end of the competition, when he promptly collapsed and is now in hospital.

The second prize-winner, Tractor No. 71, had a fuel consumption of 2.26 gal. to the acre. Pte. W. A. Ephgraves, whose home is Reading (Berkshire), is another warrior incapacitated by wounds from further active service. Some years before the War he was well known to the football public as one of the Crystal Palace eleven. A broken leg ended his career as a footballer, but did not prevent him fighting the Hun. His mate was Pte. C. Hendrick (a fork grinder of Sheffield).

Norfolk carries off second honours, with two fuel-consumption prizes; the first prize for the three-months period being won by L.-Cpl. H. Bissett and L.-Cpl. J. S. Kiddy with Fordson tractor No. 563, and a consumption of 2.49 gal. to the acre. The second prize for the period of one month was secured by Fordson Tractor No. 313, with a consumption of 1.82 gal. per acre, Pte. J. H. Kemp and L.-Cpl. J. A. Eldridge composing the team.

The other prize-winning tractors with their teams are as follows :—

Second fuel-consumption prize for the period of three months, Wiltshire ; Parrett tractor No. 5025, Ptes. E. A. Kintey and A. Hawkins, consumption 2.6 gal. per acre.

First fuel-consumption prize for the period of one month, Cumberland ; Burford-Cleveland tractor No. 5437, Sgt. P. J. Perry and Pte. Murray, consumption 1.49 gal. per acre.

Second prize for acreage for the three-months period, Oxfordshire ; Titan tractor No. 4122, Gunner Carter and Pte. Dale, 265½ acres.

First prize for acreage for the period of two months, Herefordshire ; Overtime tractor No. 5677, W. Powell and J. Wall, 257¾ acres.

Second prize for acreage for the period of two months, Worcestershire ; Titan tractor No. 3501, Ptes. S. H. Soden and A. Clegg, 191½ acres.

First acreage prize for the period of one month, Somerset ; Fordson tractor No. 319, G. Parsons and P. Pemble, 94 acres.

Second prize for acreage for the period of one month, Yorkshire (West Riding) ; Fordson tractor No. 139, Air Mechanic T. Mottram and Pte. A. V. Clarke, acreage 87½.

THE following Letter (No. C. L. 199/M. 6), dated 17th June, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Petrol and Paraffin. SIR,

With reference to the Circular Letter on the above subject, reference 62/M. 1, of the 8th February last,* the Petroleum Executive have been considering the whole question, and have asked this Department to amend that Circular Letter.

It has been found in practice that certain types of agricultural tractors that were designed to run on petrol do not run economically, even with alterations, when they use paraffin, with the result that the actual quantity of fuel which has to be imported is increased, and the efficiency of the machines is diminished.

It has been decided, therefore, to amend that portion of the letter of 8th February which asks that petrol should not be used where paraffin can be substituted for privately-owned tractors.

In future, Agricultural Executive Committees should recommend the issue of petrol for food-production purposes wherever they are satisfied that it is more suitable to the machine than paraffin. If there is any doubt as to whether paraffin or petrol should be used, preference should be given to petrol.

Questions are constantly being asked as to whether private users of tractors can obtain paraffin at the same price as this Department does. This can only be done by a consumer entering into an arrangement with one of the large oil companies to supply him in bulk at wholesale prices. In this case he would have to provide storage facilities. The Department arranges to buy at the wholesale price ruling at the date of purchase in this manner, and it is open to any individual to make a similar arrangement. Each of the oil companies now serves a definite district through one of its branches, and arrangements can be made direct with the local branch.

Except for the alterations set out above, the arrangements outlined in Circular 62/M. 1 are still in force.

I am, etc.,
(Signed) HUGH M. STOBART,
Director, Requirements and Statistics.

THE following Memorandum, dated 28th June, 1918, was issued to Agricultural Executive Committees by the Food Production Department of the Board :—

**Private Gardeners
Engaged in the Cultivation of Vegetables,
etc., and Military
Service.**

The question as to the position of private gardeners who are engaged on work of food production which may reasonably be considered to be of national importance has been under consideration. In dealing with such cases the following points should be considered by Agricultural Executive Committees.

It is of no importance whether a man was registered under the Registration Acts of 1917 and 1918 as a gardener or otherwise who was not at the time of registration occupied in food production. The occupation on 28th May, 1918, is the ruling fact. The essential point to be considered is not the acreage under cultivation but the man's occupation, the value of that occupation to food production, and the volume of produce depending on the exercise of the occupation.

If the Committee is satisfied that a man is wholly or mainly engaged in the production of food of a kind and quantity to constitute national importance, they may issue a voucher under the Agricultural Exemptions Order, 1918, protecting him from military service.

It is also to be clearly understood that if a man has already been called up the calling up notice will not operate, and should be cancelled if an Agricultural Executive Committee decides that he is eligible for a voucher under the Order.

THE following Notice was issued early in July by the Food Production Department of the Board :—

**Cultivation of Rye as
a Grain Crop.**

In pre-war days the price of rye was so low owing to the demand for a purely white flour, which can only be made from wheat, that the area devoted to the crop was very small, and it was only grown as a grain crop on the poor, sandy soils where other cereals could not be relied on. Under present conditions it deserves to be grown much more extensively. It is a safe, hardy crop comparatively unaffected by drought, frost or insect pests, and on the soils to which it is suited it yields a greater weight of human food per acre than any other grain crop. From the farmer's point of view its present price, which is the same as that of wheat, makes it an attractive crop, and the fact that it can be sown early, between the hay and the corn harvests, provides a means of lessening the rush of work in spring and autumn.

Excellent crops of rye are to be seen this year after old grass or long leys, which were broken up last year immediately after the hay was cleared, and on thin, sandy or chalky soil this plan is to be commended. The alternatives are sowing with winter oats, which will not stand a severe winter, and sowing with spring corn, which is more liable to be affected by insect pests and by drought.

If the weather allows, and the necessary tackle and labour are available, the grass may be bastard-fallowed after sowing; but unless an effective fallow is likely to be obtained the better plan would be simply to plough and press, then sow immediately. Rye may be sown almost any time during autumn and winter, but the best results are obtained

by sowing early—August and early September—whereby the plant gets a good start and a firm hold of the ground before the winter sets in.

Rye should be sown in preference to wheat on land which for any reason has been summer-fallowed and is too light for the latter crop, and it is specially adapted for sowing as a second corn crop on poor, light soils ploughed out of old grass during the past season. With the exception of wheat, rye is the grain most suitable for milling purposes, and it is desirable that there should be a very large increase in the area devoted to it. The cultivation is simple and is described in a leaflet issued by the Board of Agriculture (Food Production Leaflet No. 10), which may be obtained free on application to 3, St. James's Square, London, S.W. 1.

THE following Notice was issued early in July, 1918, by the Food Production Department of the Board :—

**The Cutting of
Mixed Crops.**

Inquiries received by the Food Production Department indicate that some doubt exists as to whether the Growing Grain Crops Order, 1918* (No. 402), which prohibits the feeding to cattle or the cutting before maturity of certain grain crops, is to be regarded as prohibiting the cutting of a mixed crop of oats and tares in a green state for feeding purposes. It is, however, to be noted that the crops referred to in the Order—wheat, oats, barley (except winter-sown barley), and dredge corn—are crops consisting entirely of grain; and the prohibition was not intended to cover mixed crops containing, in addition to a grain a non-grain plant, grown *bona fide* for soiling, ensilage or similar purpose.

THE following Notice was issued by the Food Production Department of the Board in June :—

Broken-Up Grass Land. A good deal of difference of opinion prevails amongst agriculturists as to the best time of year at which to break up grass land. It has been reported to the Food Production Department that an inquiry in Oxfordshire covering 85 cases (1,658 acres) of grass land broken up between 1st July, 1917, and 31st March, 1918, shows that failures occurred chiefly with land ploughed between November and March. Earlier ploughing gave consistently good results. The evidence suggests that generally if land is not ploughed before the hay crop is taken, it is very desirable to plough it immediately afterwards.

THE following Notice (No. C.L. 56/C.1), dated 24th May, 1918, was addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Crops Damaged by
Insect Pests.**

The Department have been asked whether farmers whose crops are destroyed by insect pests on land ploughed up in accordance with Orders served by Agricultural Executive Committees will receive compensation from the Defence of the Realm (Losses) Commission.

No claim for compensation in such circumstances has up to the present come before the Commission, but the Department have reason to think that the view of the Commission would be that damage to

* See p. 482.

crops by insect pests cannot be regarded as a direct loss due to the exercise of the powers of the Defence of the Realm Regulations such as would enable them to pay compensation, especially as damage of the kind has occurred on old arable as well as on newly-ploughed grass land, and in a great number of cases it might have been avoided if the land had been properly pressed and consolidated.

The Department cannot therefore encourage any hope that compensation will be paid by the Commission, but if there are any cases of special hardship where a farmer has suffered substantial loss, and the Committee are satisfied that he has taken all proper precautions, the Department are prepared to authorise Executive Committees in such cases to supply seed for resowing free of charge. Where farmers have already resown their land, Committees are authorised to reimburse the cost of the fresh seed if they are satisfied that the case is a proper one for such assistance. Any cases in which Committees take such action should be reported to the Department for record, with a statement of the area affected and the cost and kind of the seed supplied or paid for.

THE following Notice was issued by the Food Production Department of the Board towards the end of June :—

**Insect Pests and
Birds.**

The opinion seems to be widely held that birds are the most important factor—if not the only factor—in keeping in check caterpillars and other insect pests, and this has led to the expression of exaggerated views on the importance of birds in preserving Nature's balance. It is worth pointing out, therefore, that insects are subject to the attacks of many enemies besides birds—as, for instance, parasitic flies and ichneumons, diseases due to micro-organisms (bacteria, etc.), and parasitic fungi, while perhaps the weather exercises a greater influence on the increase or decrease of insect pests than any other factor. Birds are admittedly of great value, but it is most improbable that they alone could control any of the more serious insect pests of this country, and the same statement would apply equally to any other enemy, if the weather be excepted.

The above remarks must not be taken as disparaging the services of birds, which are incalculable, but rather as a plea for more balance in considering the subject. An ally is not less valuable because we recognise and allow for his shortcomings. For the control of insect pests we must look to all their enemies for help, and at the same time must make use of all available artificial means that have proved effective in the past.

THE following Memorandum (No. C. L. 61/C.1), dated 13th June, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Pheasants.

Representations having been made by the Ministry of Food that from the point of view of the food supply a close time for pheasants is desirable, the Board of Agriculture and Fisheries have, under the Defence of the Realm Regulation 2R, made the Destruction of Pheasants Order, 1918, under which only persons authorised by a County Agricultural Executive Committee may kill and take pheasants during the close season.

THE following Notice was issued early in July by the Food Production Department of the Board :—

The Board of Agriculture have issued an Order in terms similar to those of last year's Order, authorising the killing and taking, the buying, selling or possession of grouse and black game as from 6th August next, inclusive. This does not mean (it may be explained to avoid confusion) that *anyone* who feels so disposed is entitled to kill or take the game in question. It means merely that persons ordinarily entitled to kill this game (or to buy, sell, or be in possession of it) between the usual dates are this year enabled to exercise their rights somewhat earlier, namely, from 6th August onward to the date at which such exercise would normally be legal, if a special Order had not been issued.

AN ORDER (No. 648), dated 17th June, 1918, has been made by the Food Controller to the effect that :—

The Testing of Seeds Order, 1918. 1. *Regulation of Sale and Exposure for Sale of Seeds.*—On and after the 1st July, 1918, no person, except as hereinafter provided, or under the authority of a licence issued by or under the authority of the Food Controller shall :—

(a) Sell or expose for sale for sowing or keep deposited in any place for the purpose of sale for sowing, any seeds named in the First Schedule to this Order, unless a sample of the seed has previously been taken and tested in accordance with the provisions of this Order, either by or on behalf of the seller or at one of the following Government Stations :—For England and Wales, at the Seed Testing Station, Board of Agriculture and Fisheries, Food Production Department, 72, Victoria Street, London, S.W. 1 ; for Scotland, at the Seed Testing Station, Board of Agriculture for Scotland, 29, St. Andrew Square, Edinburgh ; for Ireland, at the Seed Testing Station, Department of Agriculture and Technical Instruction for Ireland, Upper Merrion Street, Dublin ; or

(b) Sell or expose for sale for sowing any seeds named in the First Schedule to this Order unless :—

(i.) In the case of a sale the particulars required by this Order are correctly declared to the purchaser at or before the time of sale or delivery in writing, either in an invoice of the seeds or in some other form ; provided that it shall be sufficient for the purposes of this provision if the declaration is made by reference to a printed catalogue or to a price list containing the particulars required by this Order ;

(ii.) In the case of seeds exposed for sale, a copy of the declaration required by this Order in the case of sale is conspicuously exposed on or in connection with the seeds.

Provided that in the case of a packet containing pea or bean seed (not exceeding 2 lb.), or garden turnip, garden cabbage, garden kale, kohlrabi, Brussels sprouts, broccoli, cauliflower, carrot, parsnip, beet, or onion (not exceeding 8 oz.), where the germination of the seed sold or exposed for sale is at or above that standard specified in Part (IV.) of the First Schedule, the declaration mentioned in Sub-clause (b) shall not be required, and where the germination is below that standard the declaration need only state that fact.

2. *Particulars Required to be Declared.*—The particulars required by Clause 1 of this Order are :—

(a) In all cases the name and address of the seller ;

(b) In all cases the kind of seeds sold or exposed for sale and, in the case of cereals, clovers and sainfoin, the name of the variety of the seeds ;

(c) Except in the case of cereals, the percentage by weight of pure seed, provided that in the case of seeds named in Parts III. or IV. of the First Schedule to this Order a statement that such percentage is not less than 97 shall be sufficient.

(d) Except in the case of cereals, the total percentage by weight of injurious weed seeds present, where such total exceeds 1 per cent., provided that for the purposes of this Order no seeds but those of Docks or Sorrels (*Rumex* spp.), Cranesbills (*Geranium* spp.), Wild Carrot (*Daucus carota*, L.), Yorkshire Fog (*Holcus lanatus*, L.), Soft Brome Grass (*Bromus mollis*, L. et spp.), are to be regarded as injurious weed seeds.

(e) A statement that Dodder is present if it is present to the extent of more than one seed thereof in 2 oz. in the case of Alsike Clover, White Clover, or Timothy or in 4 oz. of Red Clover, Crimson Clover or Lucerne.

(f) In the case of Sainfoin, where more than 5 per cent. by weight of Burnet (*Poterium* spp.) is present in the sample, the percentage so present.

(g) In the case of White Clover, Wild White Clover, and Alsike Clover, where more than 2 per cent. by weight of any or all of the following, taken collectively, namely, Suckling Clover (*Trifolium dubium*, Sibth.), Hop Clover (*T. procumbens*, L.), *T. parviflorum*, Ehrh., *T. angulatum*, Waldst., and *T. glomeratum*, L.) is present in the sample, the percentage so present.

(h) The percentage of seeds by number of the kind of which the sample purports to consist or of the pure seed as defined in Clause 8 (6) which germinate during a germination test, provided in the case of the seeds named in Parts II. or IV. of the First Schedule to this Order, if the percentage of germination is not less than the Standard of Germination as set out in that Schedule, a statement to that effect shall be sufficient.

(i) In the case of Clovers, Trefoil, Lucerne, Sainfoin the percentage by number of hard seeds;

(j) In the case of Perennial Rye-grass, Italian Rye-grass, Meadow Fescue, Cocksfoot, Timothy, Clovers, Lucerne, and Sainfoin seed, the country of origin (England, Wales, Scotland and Ireland being for this purpose treated as different countries) or, if the country of origin is not known to the seller, a statement to that effect;

(k) In the case of mixtures of grasses or of clovers or of grasses and clovers, which may be sold or exposed for sale for agricultural purposes, the particulars mentioned in paragraphs (a), (b), (c), (d), (e), (g), (h), (i), (j) shall be given in respect of each kind of grass or clover seed in the mixture, and the proportion by weight of each kind shall also be given, provided that in a mixture of Perennial Rye-grass and Italian Rye-grass the proportion by weight of each kind need not be stated if such mixture be declared to be a mixture of Perennial Rye-grass and Italian Rye-grass.

(l) In the case of a blend of varieties of the same species having different countries of origin, the country of origin of each of the components shall be given and the other particulars required by this Order shall be given in respect of the blend as a whole and not in respect of each component part.

(m) The month and year in which the test was made, unless such test has been made within six months from the date of sale or exposure for sale.

3. *Scales of Latitude as regards Impurities and Germination.*—The particulars of the percentage of pure seed or of the percentage of seeds which germinate during a germination test shall not for the purpose of these provisions be deemed to be incorrectly stated if they do not differ from the actual percentage as determined by a Government Station as defined in Clause 1 (a) by more than the percentage permitted by the Scale of Latitude in the Second Schedule hereto.

4. *Powers of Entry and Sampling.*—Any person authorised for England and Wales by the Board of Agriculture and Fisheries, for Scotland by the Board of Agriculture for Scotland, and for Ireland by the Department of Agriculture and Technical Instruction for Ireland (hereinafter called the Official Sampler) may take, without payment, samples of any seeds which have been sold or are being exposed for sale or are kept deposited in any place for purposes of sale, and may enter on any premises for the purpose of taking such samples. The person on whose premises the sample is taken or his representative shall give

the Official Sampler all or any of the particulars required by Clauses 1 and 2 of this Order in respect of the samples so taken, and also the name and address of the person from whom the seeds were procured. The Official Sampler shall provide the person on whose premises the sample is taken or his representative at the time of sampling with a duplicate sample in a sealed packet on which the particulars as so furnished shall be stated.

Where a sample is taken by an official sampler it shall be sent by him to the Agricultural Department for that part of the United Kingdom in which the sample was taken, and the result of any test there made shall be regarded as conclusive evidence as against the person by whom the seeds were sold or exposed for sale unless such person or his representative shall within 14 days from the date of his receipt of a copy of the certificate of such result by notice in writing to the Government Department concerned require that further portions of the sample shall be tested by each of the Government Stations named in Clause 1 (a) of this Order, in which case the sample shall be so tested and the average result of the tests by the three Government Stations shall be regarded as conclusive evidence as against the person by whom the seeds were sold or exposed for sale.

5. *Certificate of Tests.*—In any proceedings in respect of an infringement of this Order, the production of the certificate as to the result of a test carried out in England or Wales given by the Board of Agriculture and Fisheries, or as to the result of a test carried out in Scotland given by the Board of Agriculture for Scotland, or as to the result of a test carried out in Ireland given by the Department of Agriculture and Technical Instruction for Ireland shall be sufficient evidence of the facts therein stated unless the defendant requires that the person who made the test shall be called as a witness.

6. *Exception of Certain Sales.*—Samples taken in Ireland under the “Weeds and Agricultural Seeds (Ireland) Act, 1909” (9 Edw. 7, c. 31) shall be deemed to be samples taken for the purpose of this Order.

7. This Order shall not apply to:—

- (a) A sale of seeds as grown, if the seeds are not bought by the purchaser for the purpose of his own sowing; but nothing in this exception shall affect the liability of the seller for failure to deliver seed of the variety named at the time of sale;
- (b) A sale for delivery outside the United Kingdom.

8. *Definitions.*—For the purpose of this Order—

- (1) “a sample” means a sample taken in the following manner:—
 - (a) In the case of seeds sold retail and in the case of seeds sold wholesale in quantities of 4 bush. or under, portions shall be drawn from the top, middle and bottom of the bag or bags in which the seeds are contained. All the portions so taken shall be well mixed and a representative sample of the whole shall be used.
 - (b) In the case of seeds sold wholesale in quantities of over 1 sack (4 bush.) or bag, portions shall be drawn from each sack or bag by means of a sampling instrument, these portions shall be thoroughly mixed and a representative sample of the whole shall be taken; provided that when the amount sold consists of over 5 sacks or bags and not more than 10 sacks or bags portions need only be taken from one sack or bag in three; and that if the amount sold is over 10 sacks or bags and not more than 50 sacks or bags, portions need only be taken from one sack or bag in five; and that if the amount sold exceeds 50 sacks or bags portions need only be taken from one sack or bag in ten. In the case of seeds stored in heaps

or bins the sample shall be a sample from representative portions taken from various parts of the heap or bin so as fairly to represent the bulk.

(c) A sample shall be deemed to have been correctly taken if drawn from various parts of the seed whilst passing from a cleaning machine.

(2) The sizes of samples for testing shall be as follows :—

Garden Turnip.	} Not less than $\frac{1}{2}$ oz.	Wheat.	} Not less than 4 oz.
„ Cabbage.		Oats.	
„ Kale.		Barley.	
„ Kohl Rabi.		Rye.	
Brussels Sprouts.		Tares or Vetches.	
Broccoli.		Red Clover.	
Cauliflower.		Crimson Clover.	
Carrot.		Trefoil.	
Parsnip.		Lucerne.	
Onion.		Sainfoin.	
Rye-grasses.		Peas.	} Not less than 6 oz.
Meadow Fescue.		Dwarf French Beans.	
Cocksfoot.		Broad Beans.	} Not less than 8 oz.
Crested Dogtail.		Scarlet Runner Beans.	
Timothy.			
Alsike.	} Not less than 2 oz.		
White Clover.			
Field Turnip.			
Swede.			
Rape.			
Field Cabbage.			
„ Kale.			
„ Kohl Rabi.			
Mangel.			
Beet.			

(3) Where a sample has been taken in the presence of and sealed and marked by the seller or his representative, and the person drawing the sample or his representative, the sample shall be deemed to have been duly taken.

(4) When a sample of seed purporting to be one of a kind mentioned in the First Schedule to this Order contains an amount exceeding 15 per cent. by weight of one or more other kinds of seeds mentioned in the Schedule, the sample shall be deemed to be a mixture.

(5) "Impurities" mean all seeds or portions of seeds other than those of which the parcel purports to consist, whether they are those of weeds, harmless plants, or other cultivated plants, and also broken seeds of the kind of which the parcel purports to consist, so far as they are incapable of germinating, and also foreign matter, sand, grit, soil, fragments of roots, stems or flowers, single glumes, single flowering glumes and single pales, smut, ergot and other sclerotia, and also in the case of mangel and beet seed, all material which passes through a sieve having circular holes of two millimetres diameter.

(6) "Pure seed" means the seed after the impurities, as defined above, are eliminated, but, in the case of those species, varieties, stocks or strains of plants, the seeds of which cannot be distinguished from one another by expert examination, does not imply that the seed is genuine or true to name. In the case of Rye-grass, Meadow Fescue, Cocksfoot and Crested Dogtail, the seed shall be considered to be "pure" if it consists at least of the two united pales, regardless of the state of development or even the entire absence of the caryopsis or kernel within the pales.

9. *Revocation.*—The Testing of Seeds Order, 1917,* is hereby revoked as at the 1st July, 1918, but without prejudice to any proceedings in respect of any contravention thereof.

10. *Penalty.*—Infringements of this Order are summary offences against the Defence of the Realm Regulations.

11. *Short Title.*—This Order may be cited as the Testing of Seeds Order, 1918.

* This *Journal*, December, 1917, p. 1031.

FIRST SCHEDULE.

KINDS OF SEEDS OF WHICH THE SALE AND EXPOSURE FOR SALE
IS REGULATED.

Part I.

Perennial Rye-grass. . .	Red Clover.	} Under what- ever trade names sold.
Italian Rye-grass.	Alsike "	
Meadow Rescue.	White "	
Cocksfoot.	Crimson "	
Crested Dogstail.	Trefoil.	
Timothy.	Lucerne.	
	Sainfoin.	

Part II.

	Standard of Germination for Purposes of Clause 2 (h).
Wheat	90 per cent.
Barley	90 "
Oats	85 "
Rye	80 "

Part III.

Tares or Vetches.	Field Cabbage.
Field Turnip.	" Kale.
Swede.	" Kohlrabi.
Rape.	Mangel.

Part IV.

	Standard of Germination for Purposes of Clause 2 (h).
Pea	75 per cent.
Dwarf and Broad Beans	80 "
Runner Beans	65 "
Garden Turnip	80 "
" Cabbage	75 "
" Kale	75 "
" Kohlrabi	75 "
Brussels Sprouts	75 "
Broccoli	75 "
Cauliflower	70 "
Carrot	60 "
Parsnip	50 "
Beet	100 "
Onion	65 "

SECOND SCHEDULE.

SCALES OF LATITUDE.

Germination.

Where the percentage of germination stated in the prescribed particulars
are, except in the case of mangel and beet :—

	Allow per cent.
At or between 100-95 and 1-5	± 4
" " 94-90 " 6-10	± 6
" " 89-85 " 11-15	± 7
" " 84-75 " 16-25	± 8
" " 74-55 " 26-45	± 9
" " 54-49 " 46-50	± 10

In the case of mangel and beet the scale of latitude allowed shall be, where
the percentage of germination does not exceed 100, ± 10 ; where it exceeds
100, ± 15.

Purity.

Where the percentages of total pure seed stated in the prescribed particulars are :—

							<i>Allow per cent.</i>
At or between	100—90	± 2
"	"	89—80	± 4
Below	"	80	± 5

Where the percentage is stated by the seller with a range, e.g., 94—90 per cent., the percentage for the purposes of the Scale of Latitude shall be the mean, i.e., in the above case 92 per cent.

Injurious Weed Seeds.

							<i>Allow per cent.</i>
Where the percentage of injurious weeds does not exceed 2 per cent.	± 5
Exceeds 2	"	but does not exceed 5 per cent.	± 1
"	5	"	"	"	10	"	± 2
"	10	"	± 4

Notice.—By arrangement with the Board of Agriculture and Fisheries, the Board of Agriculture for Scotland and the Department of Agriculture and Technical Instruction for Ireland, the Food Controller has (until further notice) nominated those Departments, jointly, as the Government Department, by or under the authority of which licences under Clause 1 of the above Order are to be issued. All applications for licences should, until further notice, be addressed to The Food Production Department, Board of Agriculture and Fisheries, 72, Victoria Street, London, S.W. 1.

THE Food Production Department directs the attention of those who, at the Department's request have undertaken to grow sunflowers for seed purposes, to the following announcement :—

Sunflower Seed.

"The Ministry of Food announces that in the event of maximum prices being fixed for sunflower seed such prices on sales by growers will not be less than 50s. per cwt. The Ministry further announces that it will be ready to take over from Market Gardens Associations sunflower seed in sound condition, which is not sold locally, at a price of not less than 35s. per cwt., f.o.r., in bags, delivery to be made as and when required in quantities of not less than $\frac{1}{2}$ cwt."

AN Order (No. 402), dated 5th April, 1918, was made by the Food Controller to the effect that :—

The Growing Grain Crops Order, 1918.

1. A person shall not feed any cattle, or permit or suffer any cattle to be fed with any growing wheat, oats, barley (except winter-sown barley) or dredge corn in such a way as to prevent the crop coming to maturity or prejudicially to affect the growth of such crop.

2. A person shall not cut or permit or suffer to be cut before maturity any growing crop of wheat, oats, barley (except winter-sown barley) or dredge corn.

3. For the purposes of this Order :—

"Cattle" includes, in addition to cattle usually so called, horses, sheep, goats, deer and swine.

Note.—This Order was inadvertently omitted from an earlier issue of the *Journal*.

THE Food Controller, by The Potatoes (Registration of Wholesale Dealers) Order, 1918 (No. 555), dated the 22nd May, 1918, as amended by an Order (No. 623), dated 6th June, 1918, has provided that:—

**The Potatoes
(Registration of
Wholesale Dealers)
Order, 1918, as
Amended by Order
No. 623, 1918.**

1. All certificates of registration heretofore granted under the Potatoes Order, 1917,* by a Food Control Committee in Great Britain to any person as a wholesale dealer shall stand revoked as at the 1st July, 1918, so far as the same relate to eating potatoes, and as at the 1st September, 1918, so far as the same relate to seed potatoes.

2. A certificate of registration as wholesale dealer in potatoes granted or to be granted by the Food Control Committee for Ireland shall not authorise any dealings by such dealer outside Ireland in eating potatoes on or after the 1st July, 1918, or in seed potatoes on or after the 1st September, 1918.

3. Applications for new certificates of registration in Great Britain under the Potatoes Order, 1917, may be made by such persons and in such manner as the Food Controller may, from time to time direct. All such certificates shall be subject to such conditions as may be endorsed thereon or as the Food Controller may from time to time prescribe, and shall be revocable by the Food Controller at any time.

4. The holder of any certificate of registration as wholesale dealer in potatoes shall comply with such directions as to his dealings in potatoes as may from time to time be given by the Food Controller or under his authority.

5. After the date of this Order a Food Control Committee in Great Britain shall not grant to any person a certificate of registration as a wholesale dealer in potatoes.

AN Order (No. 617), dated 6th June, 1918, has been made by the Food Controller to the effect that:—

**The Potatoes
(Distribution)
Order No. 2, 1918.**

1. On and after the 10th June, 1918, until further notice, no person, other than a person licensed for this purpose by the Food Controller, shall move or consign any potatoes of the 1917 crop from Scotland to any part of England or Wales except the counties of Northumberland and Durham; and no person shall buy or agree to buy or take delivery of any such potatoes of the 1917 crop to be removed or consigned from Scotland to any part of England or Wales other than these counties except from a person so licensed.

FARMERS throughout the country are following the advice of the Ministry of Food, and are generally withholding from market those cattle which will benefit by being out at grass

**Next Winter's Meat:
Conservation Methods
and the
Revised Scale.**

during the next two months. In cases where immature beasts are brought forward for sale they are being returned by the auctioneers to their owners, or sold as stores. The expense of keeping cattle on grass is decidedly less than winter feeding, and the present low rate of slaughter means a substantial increase in production at a low cost to the producer.

Apart from the necessity of conserving the meat supply of the country, there are reasons immediately connected with the War which make it desirable that industrial districts equipped with cold storage space should be largely fed on frozen meat. Naval and Military requirements have increased the work thrown on the railways by nearly 75 per cent. over that of normal times ; yet railway and rolling stock and the number of skilled railwaymen have been diminished to serve the lines of communication in France. Live stock is difficult and troublesome to handle even with adequate labour and accommodation, and the consumption of frozen meat in the towns is one method of materially reducing the excessive strain on the railways. For the moment the rural population have the advantage, since it is as uneconomical to transport frozen meat to remote villages as to send cattle from those districts to towns. On the whole, the urban and industrial population are accepting the position as one of the minor inevitable hardships of war. Foreign beef must form a considerable proportion of the ration for some time to come ; but recent shipments of beef are of a higher grade, and there is every reason to expect a continued improvement.

Movement of cattle is being more and more narrowly restricted. The farmer has had no incentive to seek a distant market since the establishment of a uniform system of grading levelled prices, and the process of definitely tying farmers to certain markets is now nearly complete in all the live-stock areas. That market is generally the nearest to the farm ; but where there are two markets within easy reach and the farmer has been in the habit of using the more distant one and desires to continue to do so, and in other special cases, the Area Live Stock Commissioner has discretion to meet his views as far as possible.

Why the Scale was Fixed.—The difference in the cost of summer and winter feeding has been taken into account in the prices fixed for cattle between October, 1918, and September, 1919. The present level of 75s. for first-grade cattle remains in force during the next four months, while grass is abundant. The price then rises gradually to 80s. in March, and will fall to the normal level again in July, 1919. In pre-war times feeding was estimated to cost 5 per cent. more in winter than in summer, and the difference is now very much greater owing to the high price of feeding stuffs and the increased cost of labour. The fixing of prices for so long a period ahead was essential because farmers required assurance that they would be recompensed for the labour and trouble involved before providing the necessary root crops for winter feeding. The rising scale, which will carry with it as a necessary corollary a small increase in the retail price of meat, was only agreed after consideration by a joint committee of the Agricultural Advisory Committee and the Consumers' Council.

The revised scale is as follows :—

CATTLE.					
Per cwt.			Per cwt.		
October, 1918	75s.	April, 1919	80s.
November, 1918	75s.	May, 1919	80s.
December, 1918	76s.	June, 1919	80s.
January, 1919	78s.	July, 1919	75s.
February, 1919	79s.	August, 1919	75s.
March, 1919	80s.	September, 1919	75s.

In the case of sheep there is an increase of 1s. per head in November, 2s. in December, 3s. in January, 4s. in February, and between March and June of next year the increase on present prices is 5s., after which the price will again decline. (*National Food Journal*, 12th June, 1918.)

WHILE no complete data exists for a comparison of the slaughtering of cattle, sheep and pigs which took place in Great Britain during the months of January, February, March and April, 1917 and 1918, Mr. Clynes was able to give the House of Commons an approximate estimate, in which he distinguished, in regard to cattle, the numbers of oxen, bulls, cows and heifers; in regard to sheep, the total of ewes; and in regard to pigs, the total of sows. The estimate is set out in the following table :—

	Cattle.			Sheep.		Pigs.	
	Oxen and Heifers.	Cows.	Bulls.	Ewcs.	Others.	Sows.	Others.
1917.							
January ..	170,000	53,000	8,000	160,000	539,000	25,000	264,000
February ..	148,000	54,000	9,000	98,000	555,000	21,000	220,000
March ..	154,000	57,000	12,000	80,000	647,000	21,000	208,000
April ..	142,000	45,000	10,000	65,000	622,000	22,000	198,000
1918.							
January ..	102,000	42,000	5,000	166,000	707,000	25,000	176,000
February ..	96,000	39,000	6,000	53,000	386,000	16,000	139,000
March ..	103,000	40,000	9,000	48,000	512,000	10,000	88,000
April ..	97,000	35,000	9,000	31,000	534,000	7,000	72,000

(National Food Journal, 12th June, 1918.)

THE following Notice was issued by the Board on the 25th June :—
The President of the Board of Agriculture and Fisheries wishes to notify flockmasters that he has ascertained from the Food Controller that there is no intention to restrict the sale and slaughter of lambs next year. He wishes, however, to warn sheep-breeders that they must not expect to be able to obtain any concentrated feeding stuffs for lambs, or that the fixed price per lb. for lambs will be in excess of that for sheep.

WORKING horses, and, during the winter months, dairy herds, breeding stock and pigs, have the first call on the scanty stores of grain offals, meal and cake available for distribution

Cattle Feeding Stuff: among the live stock of the country. Town horses receive their allowance of oats under the Horses (Rationing) Order of the Board of Trade. The rations of concentrated food

provided under existing certificates to farm stock by the Feeding Stuff (Priority) Order of the Ministry of Food at present are :—

Calves under 6 months	½ lb. per day.
Breeding sows	4 „ „
Store pigs	1½ „ „

As regards poultry, 4 oz. of feeding stuffs per day is being allowed for selected fowls under conditions outlined in the last issue of *The National Food Journal*. * Fowls not coming under this selection scheme will be given certificates entitling them to at least 1 oz. of oats or an equivalent per hen bird per day.

No concentrated food is available at present for fattening cattle for slaughter; indeed the provision is unnecessary during the months when pasture is available, and for winter feeding the farmer is compelled to rely mainly on root crops, hay and straw. Milch cows have been excluded from the priority list until the late summer, though it has been

* See next page.

the custom in most districts to feed a certain amount of cake, even while the pastures are at their best.

The unavoidable deficiency in the quantities of concentrated food available for feeding farm stock of all kinds, and the consequent rationing of stock, have created a situation which is inducing farmers throughout the country to turn their attention to alternative methods of feeding which will render them to some extent independent of imported material. The Board of Agriculture have recently issued a series of leaflets on this question, which is of primary importance in relation to the maintenance of the home supply of meat, milk, butter, cheese and eggs under war conditions. The strain on tonnage will not cease even with the cessation of hostilities; consequently, the need for the application of the methods adopted during the present crisis will continue for some time to come. The "new" methods represent in many cases a return to an earlier system of farming before the heavy imports of oilcake simplified the problems of winter feeding.

The Feeding Stuffs Section of the Ministry of Food cannot, in present conditions, materially increase supplies of concentrated fodder, and no system of distribution, however perfect, will make good the deficiency of material. The increased use of home-grown fodder crops therefore presents the only real solution of the present difficulty.

The more important developments at the moment fall under the following heads:—

1. Soiling crops for dairy cows.
2. Silage.
3. Use of foods not hitherto fed to stock.

(*National Food Journal*, 26th June, 1918.)

THE following announcement was made by the Board on 14th June:—Mr. Prothero desires to draw attention to the fact that although

**Use of Rape Cake as
a Feeding Stuff
for Stock.**

rape cake and rape meal when properly used are good feeding stuffs, it is necessary that caution should be exercised in feeding them to stock. They should always be fed mixed with other foods which do not contain any rape meal, and only a small quantity should be given at first. Any increase that may be made should be effected gradually, and careful observation should be kept on the animals to ensure that the food is agreeing with them.

It is common knowledge that there is a shortage of feeding stuffs for live stock and poultry. For this reason a general scheme of rationing is being considered by the Ministry of Food,

**Rationing of Poultry:
Preliminary Details
of Ministry
of Food's Scheme.**

and particulars of it will be announced later. So far as poultry is concerned, the scheme will provide for a ration of food being granted for all hen birds hatched since January 1st, 1916, but no special guarantee will be given that the ration can be provided, owing to the shortage above mentioned and the demands of certain classes of other live stock.

The Ministry of Food, in conjunction with the Boards of Agriculture for England and Scotland, are introducing a separate scheme for the maintenance of the best breeds of poultry for utility purposes, and 50,000 tons of poultry feeding stuffs have been allocated to provide a sufficient ration for a certain number of such poultry. The Ministry

of Food have undertaken to carry out the scheme, and the machinery employed for the allocation of this quantity of poultry feeding stuffs will be similar to that which it is intended to employ for the rationing of all live stock. In each county, with certain exceptions, there now exists a Feeding Stuffs Committee, and it has been decided for the carrying out of the work, and having regard to the necessity for selection as well as rationing, that a Poultry Sub-Committee of the Feeding Stuffs Committee in each area should be formed, consisting of five representative poultry-keepers. Poultry-keepers will be notified in the poultry Press of a public meeting which will be held in each area at an early date for the purpose of nominating the members of the Sub-Committee for subsequent appointment by the Ministry of Food. In order to obtain representation on this Committee of Poultry-keepers from as wide an area as possible each area will be divided roughly into five sections and each section will be entitled to a place on the Committee.

Failing such nominations the Ministry of Food themselves will appoint the members of the Sub-Committee with the help of the Feeding Stuffs Committee.

In order to facilitate the proceedings at the nomination meetings referred to, notice must be given to the Ministry of Food of all names of poultry-keepers who will be nominated to the Poultry Sub-Committees to be formed in each area. The notice should take the following form:—

We, the undersigned, being poultry-keepers in the above county, give notice that we propose to nominate (Name)..... (Address)whom we regard as a representative poultry-keeper in the county of..... to serve on the Poultry Sub-Committee for the area. We have ascertained that he will be prepared to serve, if appointed.

Name..... Address.....
Signature and address of at least three poultry-keepers.

This notice must be sent to the Secretary, Feeding Stuffs Section, Ministry of Food, County Hall, London, not later than seven days prior to the date of the meeting.

Notices regarding the scheme will be issued from time to time through the poultry and farming Press and to the various poultry societies and organisations.

The Ministry of Food, in the carrying out of this scheme for the preservation of a certain number of fowls of the best breeds, ask for the full co-operation of individual poultry-keepers, poultry societies, and the poultry Press.

A brief summary of the provisions of the special scheme as applied to England and Wales is appended, and similar provisions will apply to Scotland, with slight modifications owing to certain different conditions.

In order to obtain the special ration of 4 oz. of feeding stuffs per day, fowls must come within the following conditions:—

- First Grade of Breeding Stock.**—A. Fowls must be utility breeding stock for egg production or breeding stocks of high utility quality.
B. The fowls must be pure-bred stock.
C. The standard of health of the flock must be high.
D. That for a period of at least two years this stock has been bred to meet the above requirements.
E. That the owner of the stock will give an undertaking that if his stock receives preferential treatment he will supply the public with hatching eggs, day-old chicks, and older stock at a cost no greater than his 1917 charges.
F. Selective breeding must have been practised in the flock.

Second Grade of Breeding Stock.—Stock to be included in this Grade must meet the requirements (A), (B), (C), (D), and the owner must comply with the Condition (E).

Note 1.—Although no thorough system of selecting the best females has been practised, yet if the best available males have been regularly used such stock will be worth preserving and should be included in the Second Grade. The Second Grade fowls should only receive rations after the demands of the owners of First Grade birds have been satisfied.

Note 2.—A certain proportion of the allotted 50,000 tons of feeding stuffs will be reserved for the preservation of the best utility stocks of ducks, turkeys and geese.

The ration will be supplied in the form of a grain mixture and a mash in dry form in equal proportions; but in the circumstances prevailing the contents of such mixtures may vary from time to time, and poultry receiving a ration under the special scheme can in no circumstances receive a ration under the general scheme of rationing. In order to avoid unnecessary transport, the mixtures will be made at mills near the ports.

Owners of poultry which come within the above conditions must make application in due course on the prescribed form to the Secretary of the Poultry Committee of their area, and if their applications are accepted they will receive certificates entitling them to a certain amount of feeding stuffs through the retailer (supplier) whom they have nominated in their application and with whom they must deposit their certificates. This supplier will obtain from the mills the aggregate amount to satisfy the certificates. The Poultry Sub-Committees, under the supervision of the officers of the Ministry of Food and the Board of Agriculture, will be responsible for satisfying themselves that the poultry, for which special rations are asked for or granted, comply with the proper conditions, and will closely scrutinise applications in view of the fact that the quantity of poultry feeding stuffs under this scheme is severely limited.

A wilful misstatement on the application form will constitute an offence under the Defence of the Realm Act.

Apart from the brief summary given above poultry-keepers are referred for further information to the notices which will appear from time to time in the poultry Press and to announcements which will be made at the meeting. (*National Food Journal*, 12th June, 1918.)

UNDER the rationing scheme for the preservation of the best breeds of utility poultry, arrangements have been made in each county for poultry-keepers to hold public meetings at

Rations for Poultry. which a representative poultry committee will be nominated to carry out the work of selection.

A full list of all such meetings may be had on application to the Secretary of the County Feeding Stuffs Committee, or to the Ministry of Food, New County Hall, Westminster Bridge Road, London, S.E. 1. Application forms for rations under the scheme will be available at these meetings, or thereafter from the secretary of the local committee. All applications must be made not later than 20th July. (*National Food Journal*, 10th July, 1918.)

ARTICLES and correspondence which have appeared recently in the general Press indicate that the writers are under the impression that

**Poultry Corn :
Unfounded Charges
of Profiteering.**

buyers have to pay for damaged grains double the price at which farmers are permitted to sell the best qualities. It is necessary to correct such statements, as they are entirely opposed to fact.

Under Orders issued in the autumn of 1917 by the Food Controller, the use of wheat, rye and barley is restricted to manufacture for the purposes of human food and to other licensed purposes ; but the restrictions do not apply to grain which is so badly damaged or so inferior in quality as to be unfit for those purposes.

Under the Grain (Prices) Order, 1917,* which deals with home-grown grain, the maximum price for this damaged or inferior grain is fixed at 7s. per qr. in the case of wheat and rye, and 7s. 9d. per qr. in the case of barley, less than the maximum prices for sound grain.

In the case of imported grain, damaged wheat, rye and barley are defined under the Damaged Grain, Seeds and Pulse (Prices) Order, 1917,† as meaning "such articles as are in the ordinary course of trade classed as damaged," and damaged imported oats as "oats so damaged as to be unsuitable for feeding purposes without being reconditioned by kiln drying or other mechanical treatment." The maximum prices of all these damaged imported articles are fixed by the Food Controller at prices averaging rather lower than the maximum permitted prices for damaged home-grown grain.

A difficulty arose over the price of sea-damaged grain (salved from torpedoed vessels), because of maximum prices being paid for the wet-damaged grain, so that after kiln drying and accounting for charges and loss of weight, the price of the reconditioned grain was considerably higher than the schedule price under the Order. In order to remedy this anomaly the Food Controller issued on 10th May an amending Order under which the maximum price of imported grain damaged by water and afterwards reconditioned or rendered more merchantable by kiln drying or other like treatment was fixed on and after 20th May at the schedule rates, in the original Order, for the dry weight. The following are the maximum prices ruling to-day for damaged grain :—

<i>Home-grown Grain.</i>				<i>s.</i>	<i>d.</i>	<i>lb.</i>
Damaged wheat and rye	70	0	504
Damaged barley	55	0	448
Oats improperly cleansed or containing an undue admixture of soil	43	6	336

The above are producers' prices.

<i>Imported Grain.</i>				<i>s.</i>	<i>d.</i>	<i>lb.</i>
Graded feed wheat	72	0	480
Damaged wheat and rye	55	0	480
" barley	55	0	448
" oats	41	0	336

The above prices are importers' prices *ex* quay, store, or granary at the port of discharge. (*National Food Journal*, 26th June, 1918.)

* Printed in this *Journal*, September, 1917, p. 673.

† " " " December, 1917, p. 1026.

' EXTENSIVE inquiries carried out in different parts of the country by the Ministry of Food have proved that milk production could not be maintained at its present level in many cases without a substantial increase in the prices set out in the Milk (Summer Prices) Order issued in March last.* Provision was made for this contingency in that Order (Clause 3*a*), which provided that the Food Controller might by notice fix for any area such higher prices as were justified by the local cost of production.

During the last two months Advisory Committees, on which the local Food Committees, the War Agricultural Committees, and the Ministry of Food were represented, have sat in various areas of Great Britain to consider the local cost of production. The adjustment of prices to the many variations in the costs of dairy farming in different areas shown by these inquiries would have entailed such serious complications in fixing the retail prices of milk that it has been decided to fix a flat rate all over the country sufficient to meet average costs in the districts where costs are heavy.

The addition made by the Milk (Summer Prices) Amendment Order, 1918, now issued will advance producers' prices to the following level :—

<i>England and Wales.</i>				<i>Scotland.</i>			
			<i>s. d.</i>				<i>s. d.</i>
June	1 4	June	1 4
July	1 6	July	1 4
August	1 7	August	1 6
September	1 7	September	1 8

This change will involve an automatic increase in the charge to the consumer of 1*d.* a quart. Before coming to this decision to increase the cost of a food of first necessity to the children of the nation the Ministry of Food satisfied themselves that the step was necessary in order to safeguard supplies. It has to be borne in mind that if the cost of dairying is out of proportion to prices obtainable, the farmer may turn to other more remunerative branches of farming. The course adopted was fully discussed with the Agricultural Advisory Committee and with the Consumer's Council, and commanded general assent.

It is provided that the Food Controller may, if he thinks fit, cancel or modify any contract for the sale of milk subsisting on June 9th. Where this power is not exercised, the contract price for any full milk (but not skimmed milk or buttermilk) is to be deemed to be increased by 4*d.* per gal.; but the buyer may, if he so desires, determine the contract.

The Order also extends the power already given to Food Control Committees under the terms of Clause 14 (a) (1) of the Milk (Summer Prices) Order, 1918, so that with the sanction of the Food Controller Food Control Committees may direct any person delivering liquid milk, condensed milk, dried milk, or milk preparations in their area to deliver such milk to any consumer or class of consumers in priority to any other person in their area. (*National Food Journal*, 12th June, 1918.)

* See this *Journal*, April, 1918, p. 110.

AN Order (No. 622), dated 8th June, 1918, made by the Food Controller contains the following main provisions :—

**The Milk
(Summer Prices)
Amendment Order,
1918.**

1. On and after the 9th June, 1918, until further notice, the maximum price for milk applicable under the Milk (Summer Prices) Order, 1918 (hereinafter called the Principal Order)* shall be increased by the sum of 4d. per imperial gal.
2. Where in exercise of the powers conferred by Clause 2 or Clause 5 of the Principal Order the maximum price for milk has been duly varied by a Food Control Committee: then as from the 9th June, 1918, until the Committee shall have otherwise determined, the maximum price as so varied shall be deemed to be increased by a sum at the rate of 4d. per imperial gal.
3. The following provisions shall have effect in relation to any contract for the sale of milk (excluding butter milk, skimmed milk, condensed milk, dried milk and other milk preparations) subsisting on the 9th June, 1918, so far as the same relates to milk to be delivered on or after that date.

The contract price for any such milk shall be deemed to be increased by a sum at the rate of 4d. per imperial gal., the buyer having the option (to be exercised by notice in writing to the seller before the 19th June) of determining the contract as at the 19th June, 1918. Provided that the provisions of this Clause shall not apply to such contracts as may be excepted from the operation thereof by the Food Controller.

4. The Food Controller may cancel or modify in such manner as he thinks fit any contract subsisting on the 9th June, 1918, for the sale of any milk (including butter milk, skimmed milk, condensed milk, dried milk, or other milk preparations) so far as the same relates to milk to be delivered thereunder on or after that date.

AN Order (No. 735), dated 22nd June, 1918, has been made by the Food Controller to the effect that :—

**The Milk
(Summer Prices)
Order, 1918 :
General Licence.**

Notwithstanding the provisions of Clause 8 of the Principal Order (No. 296 of 1918)* the Food Controller hereby authorises until further notice :—

- (a) Sales of milk by the pennyworth or two pennyworth ; or
 - (b) Sales of any fraction of a gill, pint, quart, or gallon of milk.
- Provided that the maximum price is not exceeded.

MAJOR WHEELER : Is it proposed to take control of the distribution of the milk supply of Great Britain ; and, if so, before coming to this decision, have the Ministry heard the views of the leading agricultural societies on the proposal ?—**Mr. CLYNES :** It has been decided with the approval of the Agricultural Advisory Committee of the Ministry of Food, on which are represented all the leading agricultural societies in the United Kingdom, that the Ministry of Food should assume the responsibility for the wholesale collection, utilisation, and distribution of milk. (*National Food Journal*, 26th June, 1918.)

* See footnote on opposite page.

AN Order (No. 578), dated 29th May, 1918, has been made by the Food Controller to the effect that :—

British Cheese (Requisition) Order, 1918. 1. This Order shall apply to all British-made Whole Milk Cheese manufactured in Great Britain on or after the 1st June, 1918, other than (1) Caerphilly Cheese, (2) Wensleydale Cheese, (3) Stilton Cheese, (4) Soft Cheese,

(5) Cheese weighing 2 lb. or less uncut.

The expression " Stilton Cheese " shall not include Loaf Cheddar.

2. (a) Every person who manufactures in Great Britain any cheese to which this Order applies shall place all such cheese at the disposal of the Food Controller and shall deliver the same to such persons and in such quantities and at such times as the Food Controller may from time to time prescribe by directions under this Order.

(b) This Clause shall not, except the Food Controller in any particular case otherwise directs, apply to a person who normally while manufacturing cheese manufactures less than 56 lb. of Cheese per week.

3. Pending any such direction no person concerned shall dispose of any such cheese, whether in pursuance of any contract or otherwise and shall take such steps as may be reasonably necessary to preserve such cheese in good condition.

4. The arbitrator to determine in default of agreement the compensation to be paid for any cheese requisitioned under this Order shall be appointed by the Lord Chancellor of Great Britain as respects cheese manufactured in England or Wales, and by the Lord President of the Court of Session as respects cheese manufactured in Scotland.

Note.—All correspondence with respect to this Order should be addressed to the Secretary, Ministry of Food (Cheese Section), Palace Chambers, London, S.W. 1.

Makers whose cheese is requisitioned will be required to deliver their cheese to the Food Controller through a factor nominated by them and approved by the Food Controller. The official forms of nomination should be in the hands of makers before the 10th June, 1918. Any maker who, by that date, has not received an official form or nomination, should at once communicate with the Ministry of Food.

AN Order (No. 579), dated 29th May, 1918, has been made by the Food Controller to the following effect :—

British Cheese (Requisition) Order, 1918: General Licence. The Food Controller hereby authorises every person from whom cheese is requisitioned under the above Order to continue until further notice to supply to his employees, and, in the case of a cheese factory, also to suppliers of milk to such factory, cheese for consumption in the household of the recipient at the first-hand price for the time being in force ; provided that returns are made fortnightly to the Food Controller of the total quantities disposed of under this licence during the preceding fortnight.

This licence may at any time be revoked by the Food Controller either generally or as respects any particular person.

In order to ensure the greatest possible output of cheese throughout Great Britain during the present season, the Ministry of Food have appointed four cheese inspectors, who are giving all the assistance in their power to cheese-makers. It has been found that in some factories, owing to local difficulties of various kinds, existing plant is not being utilised to the fullest extent, and it is the business of the new cheese inspectors to report any special difficulties in regard to supplies of liquid milk or other matters to the Ministry of Food, and to do everything in their power to assist both factory managers and farmers to increase their output to the maximum. The names and addresses of the cheese inspectors for the various divisions are :—

Bristol, Reading and Cardiff Food Divisions.—Mr. J. Hugh Mackie, Park Cottage, Castle Cary, Somerset.

Birmingham, Nottingham, Preston and Carnarvon Food Divisions.—Mr. Sutherland Thomson, Colonial House, Tooley Street, S.E.

Newcastle, Leeds, Cambridge and Home Counties Food Divisions.—Mr. H. W. Beresford, Bay Tree Farm, Milton, near Weston-super-Mare.

All Scotland.—Mr. W. McFadzean, 42, Portland Street, Kilmarnock.

Supplies of milk are still comparatively abundant, and it is regarded by the Ministry of Food as essential that as high a proportion of this liquid milk as possible should be converted into food for winter use, either in the form of dried or condensed milk or cheese.

Manufacturers of whole milk cheeses, with the exception of Caerphilly, Wensleydale or Stilton cheese, soft cheese or cheeses weighing 2 lb. or less uncut, are required to place their product at the order of the Food Controller by the British Cheese (Requisition) Order, 1918.* This requisitioning Order only applies to makers on a considerable scale, producers whose output is normally less than 56 lb. of cheese a week being excluded from its operation. Before June 10th all cheese-makers who come under the Order should have received through their Producers' Association, or from factors appointed under the distribution scheme, a form on which to nominate the factor through whom delivery should be made. By a general licence issued under the Order producers whose cheese is requisitioned are still entitled to supply their employees, and, in the case of factories, their suppliers of milk, with cheese for their own consumption at first-hand prices, provided that a fortnightly return of the quantities so supplied is returned to the Food Controller. (*National Food Journal*, 12th June, 1918.)

For the purposes of the controlled distribution of British-made cheese, the following areas have been fixed in England, Scotland and Wales :—

Control and Distribution of Cheese. 1. *South of England*, including the following counties : Northampton, Norfolk, Hunts, Suffolk, Bedford, Cambridge, Essex, Hertford, Middlesex, Surrey, Sussex, Kent, Berks, Wilts, Hants, Isle of Wight, Oxford, Buckingham, Cornwall, Devon, Dorset, Somerset, Gloucester, Channel Islands, Glamorgan, Monmouth, Brecon, Radnor, Cardigan, Carmarthen, Pembroke.

* See p. 492 of this *Journal*.

2. *North of England*, including the following counties : Northumberland, Durham, Cumberland, Westmorland, Lancashire, Cheshire, Flint, Anglesey, Carnarvon, Denbigh, Merioneth, Montgomery, Salop, Hereford, Worcester, Stafford, Warwick, Leicester, Rutland, Notts, Lincoln, Derby, Yorkshire, Isle of Man.

3. *Scotland* : The whole.

For the purposes of this scheme the expression "British-made cheese" does not cover the Caerphilly, Wensleydale and Stilton makes, nor soft cheese, nor cheeses of 2 lb. weight and less uncut ; nor does it necessarily cover the cheese of producers who do not normally make 56 lb. per week in the season, unless satisfactory arrangements can be made for the delivery of their small lots. The distribution is being kept as close as possible to the 1916 conditions. Retailers, except in special circumstances, receive supplies on the basis of their 1916 sales ; and the links between makers, factors and retailers are preserved so far as is practicable. Distribution is not rigidly limited to a percentage of 1916 supplies, and adjustments will be made where a change in the population or the occupational features of any district since 1916 makes this necessary and desirable. Makers nominate a factor with whom they did the largest portion of their business in 1916, if such a factor is within their area ; wholesalers choose factors for their supplies on the same basis ; and retailers make application similarly, either to an appointed factor or to a wholesaler.

Exportation to Ireland is forbidden under this scheme. Factors acting as agents of the Ministry of Food are responsible for payment to the maker at the rates fixed by the Food Controller, and receive, weigh, classify, store and take care of the cheese until it is required for distribution, when they perform the function of first-hand distributors. Dealers in British-made cheese will receive such cheese as far as supplies permit, but they must be prepared to accept quantities of imported cheese to make up their allotments from time to time.

Caerphilly cheese is being distributed under a scheme somewhat different in detail, though intended to be based on the 1916 distribution. Three firms have been appointed as factors under the Caerphilly scheme—Messrs. Palmer, Sons and Toogood, in conjunction with Messrs. Body and Son, at Highbridge ; Messrs. Collett, Whitefield and Co., Ltd., Colonial Buildings, Cardiff ; and Mr. L. A. Parfitt, Cambrian Road, Newport. Makers of Caerphilly cheese must nominate one of the three firms to receive their supplies. These factors store the cheese for the Ministry, and act as first-hand distributors under the instructions of the Caerphilly Cheese Committee, 76, Victoria Street, Bristol. It is proposed to requisition all Caerphilly cheese made in Great Britain. (*National Food Journal*, 10th July, 1918.)

THE following Notice was issued by the Food Production Department of the Board towards the end of June :—

Scheme for Collection of Surplus Fruit. There will be a very serious shortage of fruit in this country this year ; and it is extremely important that not a single ounce should be wasted. Although there will be

no general surplus, it is extremely probable that in certain villages, possibly even in certain suburbs, there will be more fruit grown than can be economically consumed at once, or conveniently preserved by

the ordinary domestic means. It is imperative that all such surpluses, however small, should be utilised to the best advantage.

Fortunately, this year we have the machinery for the collection of surplus fruit from practically any district and its effective preservation. Seventeen counties have already formed registered marketing societies under the scheme of the Food Production Department; fourteen other counties are about to follow suit. Very shortly it is to be hoped every county in England and Wales will have its county marketing organisation.

Even where there is no county organisation—perhaps especially where there is no county organisation—growers who are likely to find themselves at an early date with more fruit than they can consume or preserve satisfactorily, should make immediate arrangements with a view to this fruit being utilised in the national interest. They should at once notify the Marketing Section, Food Production Department, 72, Victoria Street, London, S.W. 1, of the fact that they anticipate having fruit to dispose of, and state what is its nature and the probable quantity. They need not stamp the letter making this notification.

Efforts are being made by the Food Production Department this season to bring every possible pound of fruit available into the licensed jam factories. It is believed that, although the individual surpluses may be small, a considerable total can be obtained from the private grower as distinct from the professional grower. The needs of the country in the matter of jam are approximately known, and they far exceed the fruit supplies at present in sight. The duty of every private grower, however small, is therefore obvious; he will be serving the national interest as well as his own by getting promptly into touch with the Marketing Section of the Food Production Department. From this Department he can obtain a list of the nearest jam factories and particulars of prices and consignments acceptable by rail. Where there is a county marketing society he will be brought into contact with this society; where there is no marketing society he will be advised as to the best course to pursue.

An Order (No. 641), dated the 14th June, 1918, has been made by the Food Controller and contains the following main provisions:—

PART I.—RESTRICTIONS.

The Soft Fruit (Sales) Order, 1918.

1. Except under the authority of the Food Controller a person shall not take delivery in the United Kingdom of any of the varieties of fruit mentioned in the Schedule (hereinafter called Soft Fruit) or of the pulp of any soft fruit where such soft fruit or such pulp is outside the United Kingdom on the 17th June, 1918.

2.* (a) On and after the 17th June, 1918, a person who grows in the United Kingdom any soft fruit shall not sell or deliver or offer to sell or deliver any soft fruit so grown except to—

- (i.) A licensed jam manufacturer; or
- (ii.) A recognised fruit salesman who has given to the grower a dated and written undertaking signed by the salesman that he will re-sell such fruit only to a licensed jam manufacturer.

* These Clauses have been modified by a General Licence (Order No. 732), dated 21st June, 1918.

(b) This Clause shall not apply to a grower in relation to any variety of soft fruit where his total crop of that variety grown in the United Kingdom during the 1918 season is less than 1 cwt.

3.* Where a recognised fruit salesman has brought from a grower any soft fruit to which Clause 2 applies, he shall not sell such fruit except to a licensed jam manufacturer.

4. (a) On and after the 17th June, 1918, a licensed jam manufacturer shall not buy or take delivery of any soft fruit, wherever grown, or use any fruit bought by or delivered to him for any purpose other than the purpose of manufacturing jam or pulp for sale.

(b) This Clause shall not apply to soft fruit bought by retail by and used for the household consumption of a jam manufacturer.

5. No pulp made from any soft fruit shall on or after the 17th June, 1918, be sold or delivered to any person other than a licensed jam manufacturer, or be used for any purpose except the manufacture of jam.

PART II.—PRICES.

6. On and after the 17th June, 1918, no soft fruit grown in the United Kingdom shall be sold by the grower thereof at a price exceeding a price at the rate set out against such fruit in the Schedule, free on rail, ship or barge at the grower's station, port or wharf, together with the additional charges permitted by this Order. Such price shall include all charges for picking and packing.

7. The additional charges permitted on a sale by the grower are :—

(a) Where the fruit is delivered by the grower to the buyer's premises or for sale in a market the customary charges for such delivery not exceeding in any case an amount equal to the cost of transport from the grower's station, port or wharf, to the buyer's premises or the market in which the fruit is sold.

(b) Where packages are provided by the grower :—

(i.) A charge not exceeding the rate of 40s. per ton of fruit for the use of pecks and strikes ; 30s. per ton of fruit for the use of half sieves, and 25s. per ton of fruit for the use of baskets or other usual packages (other than chip baskets and punnets), all pecks, strikes, half sieves, baskets or other packages to be returned to the grower carriage paid.

(ii.) 40s. per ton of fruit delivered in chip baskets or punnets, the chip baskets and punnets to be non-returnable.

(c) All market tolls actually paid in respect of the fruit by the grower.

(d) Where strawberries are plugged by the grower before delivery to the buyer, a sum at the rate of £4 per ton of fruit so plugged.

8. On and after the 17th June, 1918, no soft fruit grown in the United Kingdom shall be sold by any person, other than the grower of the fruit sold, at a price exceeding by more than 30s. per ton the rate set out against such variety of fruit in the Schedule, together with the additional charges permitted by this Order to be paid to the grower to the extent to which the same are payable or have been paid, and together also with the following additions where applicable :—

(a) The amount of the transport charges, if any, paid or payable by such person in respect of the fruit and not included in the sum paid to the grower ; and

(b) The amount of any market tolls actually paid by such person in respect of such fruit ;

(c) A sum at the rates and on the terms set out in Clause 7 (b) hereof in respect of packages provided by such person ;

(d) A sum at the rate of £4 per ton of fruit in respect of strawberries plugged by such person.

* See note on p. 495.

9. This part of the Order shall not apply to a sale by retail where the total quantity included in the sale is not more than 5 lb. of any one variety of fruit.

PART III.—GENERAL.

This part deals with contracts, exceptions, fictitious transactions, interpretations, etc.

THE SCHEDULE.

<i>Variety of Fruit.</i>	<i>Price.</i>
Black currants	60 per ton.
Red currants	32 "
Raspberries	37 "
Strawberries (Stirling Castle and Scarlets)	44 "
Strawberries of any other variety	40 "

THE following Letter (No. C. L. 30/H), dated 14th June, 1918, has been addressed to Horticultural Sub-Committees by the Food Production Department of the Board :—

Manufacture of Cardboard Containers for Jam.

SIR,—I am directed by the Food Production Department to inform you that in order to overcome the shortage of glass and earthenware jam jars, arrangements can be made for the manufacture of a large quantity of cardboard containers capable of holding 7 lb. of jam, provided a sufficient number are required.

The Department will, therefore, be glad if your Committee will make inquiries as early as possible and inform them whether containers of this nature will meet the need of local committees or societies who are undertaking the communal manufacture of jars.

I am, etc.,

(Signed) G. F. MIDDLETON,
For Controller of Horticulture.

THE following Letter, dated 10th June, 1918, was addressed to a correspondent by the Board :—

The Raising of Rents of Agricultural Land to Meet Increased Outgoings.

SIR,—I am directed by the President of the Board of Agriculture and Fisheries to refer to your letter of the 29th ult., and I am to say that Mr. Prothero cannot undertake to propose legislation extending the provision of the Increase of Rent and Mortgage Interest (War Restrictions) Acts to agricultural land. Those Acts were passed to restrict the rents of small houses, which otherwise would have risen to an unreasonable level owing to the stoppage of building and other causes of a local character, and as a corollary the raising of the interest on mortgages of such houses was also restricted.

In the case, however, of agricultural land there is no statutory restriction on the raising of the rent to such a figure as could have been obtained without Part I. of the Corn Production Act, and the Board have no reason to suppose that an increase of rent would be regarded as being unreasonable if required to meet additional expenditure by the landlord in consequence of the increased value of tithe rentcharge or an increase in the rate of interest on a mortgage, or other outgoings.

I am, etc.,

(Signed) F. L. C. FLOUD.

**The Strawberries
(Retail Prices) Order,
1918.**

AN Order (No. 733), dated the 21st June, 1918, has been made by the Food Controller fixing, with certain exceptions, the retail price of strawberries.

THE following Memorandum (C.L. 52/C. 1), was issued by the Food Production Department of the Board on 23rd May, and was omitted from last month's *Journal* for reasons of space :—

1. The Increase of Rent, etc., Act, 1915, restricts the power of a Court to make an order for the recovery of possession of a house let as a separate dwelling where such letting does not include any land other than the site of the dwelling-house and a garden or other premises within the curtilage of the dwelling-house and where either the rent on the 3rd August, 1914, or its then rateable value did not exceed £26.

2. As a result of the passing of the Increase of Rent, etc., (Amendment) Act, 1918, the effect in England and Wales of Section 1 (3) of the Act of 1915, which deals with this matter, as amended, is as follows, the Amendments being shown by the words in *italics* :—

No order for the recovery of possession of a dwelling-house to which this Act applies or for the ejectment of a tenant therefrom shall be made so long as the tenant continues to pay rent at the agreed rate as modified by this Act and performs the other conditions of the tenancy, except on the ground that the tenant has committed waste or has been guilty of conduct which is a nuisance or an annoyance to adjoining or neighbouring occupiers, or that the premises are reasonably required by the landlord for the occupation of himself or some other person in his employ, or in the employ of some tenant from him, or on some other ground which may be deemed satisfactory by the Court making such order, and where such order has been made but not executed before the *2nd May, 1918*, the Court by which the order was made may, if it is of opinion that the order would not have been made if this Act had been in operation at the date of the making of the order, rescind or vary the order in such manner as the Court may think fit for the purpose of giving effect to this Act.

The expression "landlord" does not include any person who, since the 30th September, 1917, has become landlord by the acquisition of the dwelling-house or any interest therein otherwise than by the devolution thereof to him under a settlement made before the said date, or under a testamentary disposition or an intestacy.

The preceding paragraph does not apply in any case where the Court is satisfied by certificate given by or on behalf of the Board of Agriculture and Fisheries that the premises in question are required for the occupation of a person engaged or employed in agricultural work of urgent national importance.

3. While the Bill was under discussion an undertaking was given by the Minister in charge that no certificate would be given without consideration as to whether it is a matter of grave national necessity from the point of view of carrying on the farm that the applicant should obtain possession of the cottage, and as to whether suitable and adequate house accommodation can be obtained for the person proposed to be evicted.

4. Where the landlord has acquired a cottage on or before the 30th September, 1917, he may obtain an ejectment order from the Court if he can satisfy the Court that he requires the cottage for the occupation of himself or of some person in his employ, or in the employ of some tenant from him, or on any other ground which would have entitled him to an order of ejectment under the Act of 1915.

5. Where, however, a landlord has acquired by purchase or on lease a cottage since the 30th September, 1917, and requires possession of it on the ground that the cottage is reasonably required by him either for his own occupation or for the occupation of a person employed by himself or by some tenant from him, he cannot obtain an order from the Court unless he produces a certificate from the Board of Agriculture that the cottage is required for the occupation of a person engaged on agricultural work of urgent national importance.

6. To enable the Board to deal with an application for such a certificate, they propose that it shall be referred to the Agricultural Executive Committee, who will be asked to inquire into the facts, and, if they recommend the application, to forward to this Department a full report on the facts with their opinion on the questions (1) whether the cottage is required for the occupation of a person engaged or employed on agricultural work of urgent national importance; (2) whether it is a matter of grave national necessity for the carrying on of the farm that possession of the cottage should be obtained; and (3) whether suitable and adequate house accommodation can be obtained for the person whom it is proposed to evict.

It would be desirable in all cases that the person proposed to be evicted should be afforded an opportunity of stating his views.

The Board will, after consideration of the Report of the Committee, decide whether a certificate should be granted.

THE rates of wages, hours, etc., stated below, have been fixed by the Agricultural Wages Board for the undermentioned counties. The rates fixed are on the basis of a six-day working week of 54 hours in the eight summer months from March to October inclusive, and of 48 hours in the four winter months from November to February inclusive, except in the case of Oxfordshire where they are on the basis of a six-day working week of 52 hours all the year round:—

District.	Wage.	Hours.	Overtime Rate.	Age.	Date of Coming into Force.
Norfolk ..	30s.	54 and 48	—	18 years.	20th May.
Northants	30s.	54 " 48	8½d. and 10d.	18 "	27th "

THE report of the Director-General of Food Production (England and Wales) for the period 19th February, 1917, to 1st June, 1918, has just been issued. Copies may be obtained

**Report of the
Director-General
of
Food Production.**

through any bookseller or direct from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2., price 6d. net.

The Report is a comprehensive review of some 50 pages of the work of the Food Production Department since its inception in February, 1917. It opens with a general statement of the principal results of the Government's policy of increasing food production in England and Wales since the beginning of 1917, and then outlines the steps taken to achieve these results. The Report deals with a number of subjects, including drainage, game, soldier and other labour, the Women's Land Army, motor tractors, horse-drawn implements, supplies of agricultural commodities, seed testing and horticulture. Much of the information has already been published in this *Journal*, chiefly in the form of Official Notices and Circulars.

PART II. of the Agricultural Statistics for the year 1917 (Cd. 9089, 1918, price 2d.) has been recently published by the Board, and gives

**Produce of Crops in
England and Wales,
1917.**

returns of the produce of crops for England and Wales in 1917, with summaries for the United Kingdom. An interesting feature is the statement of the total output of the main farm crops in the United Kingdom during the four years from 1914 to 1917, and the increased contribution of home agriculture to the food supply for the year under review. The active intervention of the State to increase home production was only partially operative in the harvest of 1917; the full effects will become more apparent in the harvest of the present year.

THE Meteorological Office will, as in past years, but subject to certain restrictions, supply forecasts of weather by telegraph to persons

**Harvest Weather
Forecasts.**

desirous of receiving them, upon payment of a registration fee of 1s. and the cost of the telegrams, computed at 9d. per day. The supply of forecasts will continue until 30th September. The forecasts are drawn up each week-day at 4.30 p.m., and refer to the probable weather during the 15 hours from 6.0 a.m. to 9.0 p.m. on the next day. The addition of a "further outlook" and the issue of notifications in connection with spells of settled weather are suspended during the War.

Applications for the forecasts should be sent to the Director, Meteorological Office, South Kensington, London, S.W. 7, with a cheque or postal order payable to the Meteorological Committee, to cover the cost of the telegrams for the period, which should not be less than six consecutive days, during which the forecasts are to be sent.

THE following Notice was issued by the Board on the 27th June :—
 The Board of Agriculture and Fisheries have awarded the Fream Memorial Prize for 1918 to Mr. Leonard C. Robinson, a student of the Harper Adams Agricultural College, Newport Salop, who took the highest marks at this year's examination for the National Diploma in Agriculture.

THE following announcement was made by the Board on 14th June :—The President of the Board of Agriculture and Fisheries has appointed a Committee to consider and report how Government stores which may become available after the close of the War can best be utilised for agricultural and horticultural purposes ; and what methods of purchase by farmers and others should be adopted.

The Committee will be constituted as follows :—

The Earl Grey.	Mr. John W. B. Pease, J.P.
M. J. S. Gibbons.	Captain Sir Beville Stanier, Bt., M.P.
Mr. W. R. Hopkinson.	Mr. Robert Stephenson.
Dr. F. Keeble, O.B.E., F.R.S.	Mr. Nigel Walker.
Mr. Douglas Newton.	Major the Hon. Edward F. L. Wood, M.P.

The Secretary of the Committee is Mr. E. G. Haygarth Brown, of the Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. 1.

THE following is a list of Retail and Wholesale Maximum Prices of certain agricultural commodities fixed by the Food Controller (extracted from recent issues of the *National Food Journal*) :—

RETAIL MAXIMUM PRICES.

Butter , a rate not exceeding actual cost as defined by the					
Order to the retailer by	2½d. per lb.
Government Butter	2s. 4d. „
Cheese , an addition to actual cost to the retailer as defined					
by the Order, not exceeding	2½d. per lb.
Government Cheese	1s. 4d. „
Damaged Grain, Seeds, and Pulses—					
For quantities not exceeding 7½ qr., add to traders' prices	4s. per qr.
For quantities of less than half a qr.	8s. „
Milk (Summer prices, unless varied by local Food Control Committees, subject to the sanction of the Food Controller)—					
June and July	2s. 4d. per Imp. gal.
August and September	2s. 8d. „ „
(These prices do not apply to Ireland.)					

Potatoes, Early (1918 Crop)—

(Imported and Home-Grown.)

From June 16-30	3d. per lb.
„ July 1-15	2½d. „
„ „ 16-31	2d. „

Potatoes : Ware (1917 Crop)—

Sold by grower, quantities less than 1 cwt. 1d. per lb.

Sold by retailer, the following scale :—

Retailer's Buying Price per Cwt.	Highest Authorised Retail Selling Price over the Counter.		
	Per Stone of 14 lb. for Lots of 14 lb. or more.	Per Half Stone for Lots of 7 lb. or more, but less than 14 lb.	Per lb. for Lots of less than Half Stone.

Wholesalers' prices: average profit during any week		
not to exceed	..	7s. 6d. „

Mr. Philip Savill, The Woodlands, Chigwell, a member of the Stratford (London) Bench, was fined £5 for aiding and abetting William Salter, his coachman (fined 40s.), in feeding a horse with cereals.

Prosecutions of Farmers, etc., under Statutory Rules and Orders. Mr. Alfred Gravely Howard, Burnt House, Chigwell, a J.P. for West Ham, was fined £5, and George James White, his coachman, £2, in respect of the feeding of a horse on "flaked

horse food," which contained crushed oats.

Belvoir.—Fines amounting, with costs, to £45 were imposed on Arthur Hoy Hickson, Bottesford, for extracting less than the prescribed percentage of flour from wheat.

Haywards Heath.—S. Caffyn, of Cuckfield, was charged with failing to send in monthly returns for 20 weeks. Mr. C. H. Hornby, of the Ministry of Food, pointed out that, when millers did not forward these returns, it was impossible to know whether the regulation flour was being made. The Bench imposed fines amounting to £21, with 10 guineas costs. (*National Food Journal*, 22nd May, 1918.)

Scarborough.—Messrs. G. Turnbull and Sons, Allerston, were charged with failing to obtain the minimum percentage of flour in respect of four monthly periods. Mr. C. H. Hornby, Ministry of Food, pointed out that, an inspector having considered the flour they were using much too white, frequent warnings had been given. The wastage of bread over the period represented 3,397 four-pound loaves. Mr. Hart, defending, urged that they had done everything to comply with the Orders, and that the offence was purely technical. Fines amounting to £60 were imposed, with £30 costs.

Whitby.—Messrs. H. B. Bell and Son, Ruswarp, were fined £22 for a similar offence, with 20 guineas costs.

Wimborne.—J. F. Hatchard, Walford Mills, was charged on 31 summonses with failure to make monthly and weekly returns as required by the Flour Mills Order. Fines amounting to £31, with £15 costs, were imposed.

Blackwood (Mon.).—Richard Richards, farmer, and Richard Williams, wholesale meat buyer, were fined £50 each, with 10 guineas costs, on a sale of ungraded cattle outside a market. (*National Food Journal*, 12th June, 1918.)

Brentwood.—Thomas Knight, South Weald, was mulcted in the sum of £30 10s., fine and costs, for selling unmarketed sheep for slaughter and Frank May, who had slaughtered them, £15 5s.

Lincoln.—Frederick Chapman, 25, Dale Street, and Richard Parker, were fined, respectively, £10 and £5 for feeding rock cakes to pigs. About 7 stones of these cakes, which the executive officer and a police sergeant tasted without ill effects, were found in two swill tubs. They had been bought from an Army canteen. (*National Food Journal*, 26th June, 1918.)

Pontefract.—Arthur Stubbs, farmer, and Thomas Meays, butcher, were fined £20 each for selling and buying a calf outside a market. (*National Food Journal*, 10th July, 1918.)

MISCELLANEOUS NOTES.

THE *International Crop Report and Agricultural Statistics* for June, 1918, issued by the International Institute of Agriculture, contains estimates of the production of the cereal

Notes on Crop Prospects Abroad.

crops of 1918 in certain countries in the Northern Hemisphere. **Wheat.**—The production in Canada, United States, British India, and Tunis is estimated at 203,684,000 qr. this year, against 158,803,000 qr. last year, or an increase of 28·3 per cent. **Rye.**—The estimated production in Canada and the United States is placed at 10,116,000 qr. in 1918, against 7,465,000 qr. in 1917, or an increase of 35·5 per cent. **Barley.**—The production in Canada, United States, and Tunis is estimated to amount to 37,274,000 qr. this year, against 32,666,000 qr. last year, or an increase of 14·1 per cent. **Oats.**—It is estimated that the total yield in Canada, United States, and Tunis, will amount to 208,079,000 qr. in 1918, or an increase of 0·5 per cent. compared with 1917, when it amounted to 207,068,000 qr.

The condition of the crops in other countries on the 1st June, 1918 (100 being taken to represent the average yield in the last 10 years), is given as follows :—*Wheat*.—Scotland, 110 ; Ireland, 115 ; Sweden, 103 ; Switzerland, 94. *Rye*.—Sweden, 107 ; Switzerland, 100. *Barley*.—Sweden, 103 ; Switzerland, 100. *Oats*.—Sweden, 98 ; Switzerland, 94.

Netherlands.—According to a report received from H.M. Consul-General at Rotterdam on the state of agricultural produce on 14th June, the weather has been very dry and many crops have lost condition in consequence. The general prospects throughout the country are as follows : (100=excellent ; 90=very good ; 70=good ; 60=fairly good ; 50=moderate ; 40=fairly bad ; 30=bad ; 10=failure. The figures in brackets give the condition of the crops on 20th April) :—Winter wheat, 69·8 (72) ; summer wheat, 67·7 ; winter rye, 70·1 (70) ; winter barley, 67·8 (67) ; summer barley, 63·7 ; oats, 58·5 ; potatoes, 68·6. The fruit prospects are not promising. Insect pests have been very troublesome, owing chiefly to the dry, sunny weather, and night frosts and drought have done harm.

France.—According to the official report of the Ministry of Agriculture on 1st June the weather during the first fortnight of May was wet and cold, but during the rest of the month warm and dry, except for occasional thunderstorms, hail, and floods in some parts. The conditions during the latter half of the month were in general favourable for agricultural work, and potato and artichoke planting, and maize, buckwheat, bean, and beetroot sowing, were carried on satisfactorily. Growing crops recovered from the check they had received earlier, and their condition greatly improved. Cereals on the whole look well, in some cases very well. Hay-making has begun in some districts, with the prospect in general of a good yield. Potatoes, which suffered from excess of moisture, have been replanted where necessary, and the crop now presents a satisfactory appearance. Fruit, especially stone fruits, suffered seriously from April frosts, and in the cider making districts the crops of apples and pears will be very scanty.

A later report, dated 1st July, states that the dry weather of the latter half of May continued through June, and spring barley and oats and most root crops suffered somewhat from want of moisture. Autumn cereals, except on very light soils, were not injured and present a very promising appearance. The yield of hay, though rather light, is of good quality. (*Journal Officiel*, 1st July, 1918.)

Canada.—The High Commissioner for Canada, in a report dated the 17th June, states that the estimated yield of this year's grain crops is as follows :—wheat, 313,576,000 bush. ; oats, 494,604,000 bush. ; barley, 65,285,000 bush. ; and rye, 4,000,000 bush.

United States.—According to a report issued by the Statistical Bureau of the Department of Agriculture the condition of the crops on 1st July was as follows (1917 figures in brackets for comparison) : Winter wheat, 79·5 (75·9) ; spring wheat, 86·1 (83·6) ; barley, 84·7 (85·4) ; oats, 85·5 (89·4) ; winter rye, 80·8 (79·4) ; maize, 87·1 (81·1). The yield of winter wheat is now estimated at 557,000,000 bush. as compared with 418,000,000 bush. last year ; spring wheat 334,000,000 bush. against 232,000,000 bush. ; barley 230,000,000 bush. against 209,000,000 bush. ; oats, 1,437,000,000 bush. against 1,587,000,000 bush. ; and winter rye, 82,000,000 bush. against 60,000,000 bush. in 1917. The area under maize is estimated at 113,835,000 acres as compared with 121,000,000 acres last year, and the yield at 3,160,000,000 bush. against 3,159,000,000 bush. last year. The amount

of old wheat in farmers' hands is estimated at 8,000,000 bush. compared with 15,720,000 bush. a year ago. (*Broomhall's Corn Trade News*, 10th July.)

Egypt.—The Bulletin of the Ministry of Agriculture, dated 30th April, gives the condition of the wheat crop as 98 to 101 per cent. of average; barley, 101 to 105 per cent.; beans, 102 to 104 per cent. (*Broomhall's Corn Trade News*, 18th June, 1918.)

THE Crop Reporters of the Board, in reporting on agricultural conditions in England and Wales on the 1st July, state that the weather has been generally cold and dry, and the lack of moisture has checked growth, particularly on light soils. Wheat promises to be the best of the cereal crops; it has made good progress and is now coming well into ear. In some districts spring wheat has suffered from the drought. The yield in nearly all districts is expected to be over the average. Barley, for the most part, looks well, but has suffered from the absence of rain, particularly on sandy soils, and is not expected to give an average yield. Oats are not so promising, and have suffered from the drought and wireworm, and the yield is likely to be below average. Straw is generally short. Beans and peas are satisfactory, and should give an average crop.

Potatoes have come up well, and are strong and healthy, though the growth has been retarded by the cold weather and the lack of rain. There is very little mention of disease, and the yield is expected to be about average.

Turnips and swedes have suffered from the dry weather and attacks of "fly." A good deal has had to be re-sown, and germination is backward in these areas. Mangolds have also suffered from the same causes, and the yield is likely to be substantially below the average.

The hay harvest is generally earlier than usual, and much has been secured under favourable circumstances and in good condition. The yield of seeds hay is likely to be about average, but that of meadow hay slightly under average.

Grass has been fairly plentiful, but pastures are now getting bare and rain is badly required. Stock are in a healthy condition and for the most part doing well. In some districts the supply of milk is falling off.

The cold nights and lack of rain have retarded the growth of hops, and the bine is very backward. Attacks of aphid have been very prevalent, and washing has been general. The yield in Kent is only expected to be about three-quarters of a crop, and in the western counties but little more than half the average.

All classes of orchard fruit have done badly owing to early frost and insect attacks, and in many districts the crops are failures. The yield of apples, plums, and pears is likely to be very small, but cherries promise a little better, although much below the average. The yield of small fruit of all kinds is also below average.

The supply of labour is generally deficient, but the shortage has to some extent been relieved by the employment of women, soldiers, and German prisoners, while the fine weather has enabled the hay harvest to be proceeded with rapidly.

Summarizing the returns, and expressing an average crop by 100, the condition of the crops on the 1st July indicated probable yields per acre which may be denoted by the following percentages :—Wheat, 103 ; barley, 98 ; oats, 95 ; beans, 101 ; peas, 99 ; potatoes, 100 ; mangolds, 93 ; seeds hay, 99 ; meadow hay, 97 ; hops, 70.

THE following local summaries give further details regarding agricultural labour in the different districts of England and Wales :—

Northumberland, Durham, Cumberland, and Westmorland.—Labour is still very scarce in some districts, but in others sufficient, so far, thanks partly to the easy hay harvest.

Lancashire and Cheshire.—The supply of labour is still very deficient.

Yorkshire.—The deficient supply of labour is causing farmers a good deal of anxiety, and work proceeds slowly. Good horsemen are scarce, and extra labour is needed for hoeing turnips. Women have helped greatly, and where soldiers are also available work has been kept in hand.

Shropshire and Stafford.—The supply of labour is still deficient, very little casual labour being obtainable for the hay harvest and hoeing.

Derby, Nottingham, Leicester, and Rutland.—The usual labour is increasingly deficient, but the dry weather and slow rate of growth have made it possible for the work to be kept fairly well in hand by substitutes.

Lincoln and Norfolk.—Very little of the usual labour is now available, but work has been so far kept in hand by substitutes.

Suffolk, Cambridge, and Huntingdon.—The normal male labour is everywhere increasingly deficient.

Bedford, Northampton, and Warwick.—The usual labour is deficient, but the work has been mostly done by substitutes and is not behindhand. Wages still tend to increase.

Buckingham, Oxford, and Berkshire.—Labour is scarce, but so far has been sufficient, especially as so little fruit picking has been done.

Worcester, Hereford, and Gloucester.—Labour is deficient in most districts, but with the help of soldiers and women and prisoners of war the work is being got through, though sometimes with difficulty.

Cornwall, Devon, and Somerset.—Labour is generally deficient, but the fine weather has enabled the work to be accomplished with the help of soldiers and women.

Dorset, Wiltshire, and Hampshire.—Very little of the usual labour is now available, the work, for the most part, being done by substitutes.

Surrey, Kent, and Sussex.—The usual labour is increasingly deficient, and wages are high, but, in general, the work has been kept in hand so far with the help of substitutes.

Essex, Hertford, and Middlesex.—The supply of labour is deficient, but the general situation appears about the same as last month.

North Wales.—In most districts the supply of labour is very scarce, but in others there is sufficient with which to carry on.

Mid Wales.—The usual supply of male labour is increasingly deficient in all parts of the division.

South Wales.—The supply of labour, especially casual, is very scarce in most districts.

THE following statement shows that according to the information in the possession of the Board on 1st July, 1918, certain diseases of animals existed in the countries specified :—

Animal Diseases on the Continent. *Austria (on the 29th May)* Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Denmark (month of April).—Anthrax, Swine Erysipelas.

France (for the period 19th May—1st June).—Anthrax, Black-leg, Foot-and-Mouth Disease, Glanders, Rabies, Sheep-pox, Sheep-scab, Swine Erysipelas, Swine Fever.

Holland (month of April).—Anthrax, Foot-rot, Swine Erysipelas.

Hungary (on the 29th May).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Italy (for the period 3rd—9th June).—Anthrax, Black-leg, Foot-and-Mouth Disease (1,253 outbreaks), Glanders, Rabies, Sheep-scab, Swine Fever.

Norway (month of May).—Anthrax.

Spain (month of January).—Anthrax, Black-leg, Dourine, Glanders and Farcy, Pleuro-pneumonia, Rabies, Sheep-pox, Sheep-scab, Swine Erysipelas, Tuberculosis.

Sweden (month of May).—Anthrax, Black-leg, Swine Erysipelas, Swine Fever.

Switzerland (for the period 3rd—9th June).—Anthrax, Black-leg, Swine Fever.

No further returns have been received in respect of the following countries: Belgium, Bulgaria, Germany, Montenegro, Rumania, Russia, Serbia.

THE JOURNAL OF THE BOARD OF AGRICULTURE

Vol. XXV. No. 5.

AUGUST, 1918.

EDITORIAL NOTES.

THE Central Agricultural Advisory Council, the President of which is the Right Hon. R. E. Prothero, M.V.O., M.P., President of the Board of Agriculture and Fisheries, is an amalgamation of the Agricultural Advisory Committees of the Ministry of Food and the Board of Agriculture, and consists of representatives chosen from the chief agricultural organisations of the United Kingdom, with the addition of members nominated by the Departments concerned. At its first meeting on the 16th July, Lord Selborne was elected Chairman, and Sir Charles Bathurst and Dr. Douglas, Vice-Chairmen.

The terms of reference for the Council were: "To advise the Ministers of the Board of Agriculture and the Ministry of Food on matters of policy involved in the control during the War of the prices, distribution and production of agricultural products." In his opening remarks the President pointed out that the members of the Council were there in two capacities: (1) as representatives of a great and important industry, and (2) as an assembly of farmers who as loyal patriotic subjects, were asked to be just not only to their own industry, but to all the other interests and industries of the vast host of inhabitants affected by their advice. He was sure that they would feel the serious responsibility which was entailed by their decision as advisers in the national interest. On his election as Chairman, Lord Selborne said that he accepted on condition that the Council be consulted by the four Departments concerned on proposals relating to agriculture before they had reached a point when reconsideration was impossible, or even had begun to come to a provisional decision, and by other Departments, such as the War Office, which dealt with agricultural products other than food, *e.g.*, wool and hay. A note of the proceedings of the first two meetings is given at p. 604.

SPECIAL attention is directed to the Report of the statement made by the President of the Board in the House of Commons, on 18th July (p. 521). In his statement, the President dealt generally with the work of the Board during the preceding 18 months, and showed that a good deal had been accomplished despite the many difficulties with which the Department had had to contend.

AT a meeting at the Cannon Street Hotel, on 15th July, under the auspices of the Agricultural Seed Trades Association of the United Kingdom, Mr. Lawrence Weaver, C.B.E., Controller of Supplies, Food Production Department, announced that Sir Robert McAlpine and Sons had contributed to the endowment of the National Institute of Agricultural Botany a sum of £10,000 in addition to £1,000 a year for five years, and five other gentlemen had given £1,000 each, while the Association of Corn and Agricultural Merchants and the Millers Association had also opened subscription lists for their members. At the close of the meeting it was announced that the Seed Trade had contributed over £10,500, which has since increased to £13,000. Mr. Weaver explained that none of the money subscribed would be used for building the Official Seed Testing Station. This would form part of the Institute, but its cost would be provided by the Board of Agriculture. The Trust Fund, so far, amounts to about £36,000 and it is hoped will reach £50,000.

THE feeding trials conducted in England, Scotland, and Ireland, of which an account is given by Professor Wood on p. 549, show fairly clearly the differences in results when store cattle are fed with and without cake. At the present time when feeding stuffs are so scarce, farmers should pay special attention to the results of these experiments.

IN reply to a question put by Lord Selborne in the House of Lords on 8th August, Viscount Peel replied that the question of afforestation was referred by the War Cabinet to a Sub-Committee of Ministers who reported generally in favour of the proposals of the Forestry Sub-Committee of the Reconstruction Committee, and their Report has been accepted by His Majesty's Govern-

ment. Viscount Peel stated that a central authority for afforestation for the United Kingdom would be set up, and a policy of planting would be pursued with the least possible delay. (See also p. 524.)

HORSE owners should take particular note of the statement as to parasitic mange which is given on p. 581. Evidence is fast accumulating that this disease is becoming very prevalent, and farmers should take every possible step to prevent their animals becoming affected. Should the disease be discovered, the remedies recommended should be immediately applied.

ATTENTION is directed to the section of the Report of the Agricultural Policy Sub-Committee of the Reconstruction Committee which deals with the importance of agricultural organisation and co-operation. The Committee suggest that the outstanding feature of the agricultural industry is its isolation, and that in this age when combination becomes daily more necessary in order that the small man may enjoy some share in the growing advantages of the big transaction, agriculture must not stand aloof, or it will eventually be forced to the wall. No movement will do more to establish the strength of agriculture than co-operative organisation, and this applies no less to the large than to the small farmer. The agricultural organisation societies should play an important part in the future of this movement. At the end of the War there will be an immediate call for the development of the work of such societies, and a definite detailed policy will have to be formulated. In regard to England and Wales the Agricultural Organisation Society foresees an increasing need for the spread of business habits among agriculturists, especially in the matter of book-keeping and accounts.

ROADSIDE grazing of stock (see p. 586) is commonly practised in some parts of the country, and there would appear to be no reason why, in view of the ploughing up of grass land and at times when the pastures are somewhat bare, it should not become more common still. There are always difficulties, particularly in connection with the rights concerned, but good will and tact might well

enable all difficulties to be overcome. The grazing of cows along the roadside may give one or more of the pastures a rest and effectively serve to keep up the yield of milk. The labour side of the question is not serious, as it is usually met by the part-time employment of one or more boys or girls.

The note published at p. 576 is very suggestive of what can be done to improve derelict land and increase food production. Resource, skill, and determination to succeed in improving such land, may be expected to be fruitful in results, though difficulties are likely to arise. The County Agricultural Executive Committees, however, will do all they can to assist those who need help, and farmers need not hesitate to consult them and invoke their aid.

THE Army Council recently decided to release several thousand soldiers on agricultural furlough for harvest work. These men were to be distributed among the counties where labour assistance for the harvest was most needed. Farmers requiring additional labour should apply at once to their County Agricultural Executive Committee who will arrange with the Commandant of the local distribution centre. Also, of the 30,000 men who were to be called up for the Army 9,000 were left until after harvest. The Ministry of National Service was arranging for the employment of about 15,000 men from public and elementary schools, scouts' divisions, etc.; over 17,000 prisoners of war were at work on the land in Great Britain early in August; and several thousands of workers were available from other sources (war agricultural volunteers, seasonal workers, etc.). At the beginning of August the number of men in agricultural companies numbered about 70,000 and these are a permanent reinforcement to agriculture. Finally, on 8th August, Lord Clinton, Joint Parliamentary Secretary to the Board of Agriculture, in reply to a question in the House of Lords by Lord Selborne, said he was authorised to give an undertaking that no more keymen would be withdrawn from agriculture, subject, he imagined, to no urgent need arising for the Army which was not then anticipated. He understood that his authority went so far as to say that the keymen included in the 9,000 men to be left until after harvest would not be taken.

THE BOARD OF AGRICULTURE AND FISHERIES AND INCREASED FOOD PRODUCTION.

IN a speech in the House of Commons on 18th July, the Right Hon. R. E. Prothero, M.V.O., M.P., President of the Board of Agriculture and Fisheries, made a statement as to the operations for which the Board are responsible.

Agricultural Wages Board.—Mr. Prothero dealt first of all with the Agricultural Wages Board which has been set up in accordance with the Corn Production Act, and stated that “there are thirty-nine District Wages Committees. They are all also set up, and the Board has already issued notices for twenty-two counties of the statutory rate of wages. The notices are already advertised for another eighteen, and in the course of time the rates will be fixed in the other counties which are left out at present. The wages are mainly in the region of about 30s. a week. Whether they can be continued to be paid depends largely upon prices. Of course other things may help. Better organisation of labour and increased machinery may help if we can increase the produce of the land without increasing appreciably the cost of production. That, again, will be of very material assistance, and that form of help we expect from men of science. It is, therefore, a natural transition, I think, to turn from the Wages Board to scientific research.

Research.—“This is a field which is very large. To describe it in detail would occupy all the time at my disposal. I can only allude to the work of Dr. Russell at Rothamsted on the problems raised by the conversion of grass land into arable land and the research for an efficient soil insecticide. Again, I must only allude to the work done at Cambridge by Professor Wood and Mr. Hopkins on animal nutrition, and particularly on economy in beef production. I desire to illustrate the possibilities of scientific research in agriculture from the plant-breeding work of Professor Biffen at Cambridge. It is almost one of those romances in which science abounds. It is more than fifty years since the Abbot Mendel discovered the laws of inheritance. Those laws remained unrecognised until the present century, but on them is founded a new science. It has been discovered that you can create a new variety of plant by transferring to it the hereditary inherent characteristics of other varieties of plants. The result of this is most remarkable. Instead of having to wait for the chance discoveries of nature

we can deliberately sit down and manufacture the kind of plant that we want. The experiments of Professor Biffen with rust-resisting varieties of wheat are typical of the process. After examining a number of varieties of foreign wheat he discovered a Russian wheat called *Ghirka*, which resists rust. Now rust destroys annually thousands of quarters of wheat, but this *Ghirka* wheat was of no use to the British farmer because its yield was miserably low. But Professor Biffen, by using the Mendel system, was able to transfer the rust-resisting quality of *Ghirka* to a high-yielding English wheat, and though that wheat has now been in use for several years it has shown no tendency whatever to revert either to the rust tendency of one parent or the low-yielding tendency of the other. He has now produced a wheat which produces a high quality of straw—a fine, stiff, upstanding straw—and a high quality of yield of grain, so much so that without pushing it will produce 42 bush. to the acre, and by pushing up to 72 bush. to the acre. It also possesses a very high quality of disease resistance, and it combines with these qualities the quality of strength, which is so highly valued by both millers and bakers, and which is recognised in increased prices.

“Hitherto the plant-breeding work has been hardly applied to any of the crops of the farmer except wheat—though it has been applied partly to barley—and mainly to wheat suited to the Eastern Counties. But suppose you apply it to the wheats and barleys used in other districts, to oats and rye, to temporary grass and potatoes. There is an extraordinary list of possibilities opened to the British farmer. If, for instance, you could produce a potato which was immune from blight and immune from wart disease, it would be an invaluable boon to English agriculturists, and there is every prospect that that may be achieved. If any millionaire is to survive the vigilance of the Chancellor of the Exchequer he cannot do better than turn his attention and his money to the Plant-Breeding Institute at Cambridge and to the Institute of Applied Botany which we are endeavouring to found there, and I believe that he would confer a great boon upon the agriculture of this country. . . .

Cheese Schools.—“There is one small piece of practical work to which I should like to allude in passing. That is to the cheese-making schools which have now been started in a large number of counties. That movement started in the autumn of 1915. It has been greatly developed under the pressure of the War, as to the most economic use to be made of surplus milk, and we have them now in some 33 counties, and we have

co-operative cheese schools also in another seven counties. In some counties they have taken a firm root and they have established a real industry.

Milk-recording Societies.—"One deplorable result of the War is that milk-recording societies have practically come to a standstill. Anybody who has had experience of the value of these societies will regret that result of the War. There are only 25 of them now and the loss is very great. I wish they could be extended.

Farm Colonies.—"The Board's Report about the farm colonies has come up for discussion on the Bill extending these farm colonies. Nobody, I venture to say, knows better than I do how inadequate a provision has yet been made, or even foreshadowed, for the great want that there will be for land after demobilisation. The Board's plans for providing for the wants of demobilised soldiers and sailors have been before the Government for some time and are still under consideration. . . .

Live Stock.—"As to live stock, veterinary science has now got a magnificent laboratory equipped in Surrey, and I hope that the future use of that laboratory will result in great advances in veterinary science. I may say that the health of the live stock has been, on the whole, extremely good. There has been an outbreak of parasitic mange among horses, but there is a great reduction in the sheep-scab, and up to a very few days ago I should have been able to say a great reduction in swine fever, and that in spite of the fact that the Board, early last year, relaxed its Regulations in order to encourage and maintain the pig population of the country. The numbers of live stock in England and Wales may be of interest to the House. I should like to compare the Returns of 4th June, 1914, and 4th June, 1917, with the estimate for 4th June, 1918. The number of dairy cattle shows an increase in the present year on the figures of both preceding years; that of beef cattle over one year old shows a slight diminution on the figures of 1917, but an increase on those of 1914; that of all cattle under one year shows an increase over both periods. The total net result is a diminution of 27,000 head of cattle on the figures of 1917, and an increase of 330,000 on the pre-war period of 1914. The number of sheep shows a decline, and it is a decline on the figures of 1914, and a smaller decline on the figures of 1917. That result is mainly due to the disastrous lambing season of 1917. It has already been partly counteracted by the more favourable season of 1918.

"The pig population of the country declined last year very seriously, from October onward. That decline has, however, now been arrested. The Board has always been in favour of as large an increase in pigs as possible in this country, provided that pig-keepers do not trespass too largely on the breadstuffs of the people for the food of pigs. The hon. Member for East Grinstead (Mr. Cautley), now gives us the benefit of his valuable help, unpaid, in looking after the pig industry in this country. He has already achieved valuable results. . . .

"Individual landowners have taken up this question of increasing the number of pigs with great vigour. In Gloucestershire, for instance, the hon. Member for the Wilton Division (Sir C. Bathurst), a few weeks ago, had already been instrumental in establishing 65 pig clubs. The Rural League set up 130 in different parts of the country. We have many agencies working in the same direction, and were I quite sure of the supply of feeding stuffs and of its distribution I should regard the situation as promising. . . .

Forestry.—"In forestry the principal feature of the period under review has been the admirable Report of the Forestry Sub-Committee of the Reconstruction Committee. . . . I feel sure that the Report lays down the lines on which forestry must for the future advance. The Board has already, in consultation with the Minister of Reconstruction, formulated its plans. We are ready to start as soon as we have the funds, and we are making certain preparations. We have got in the Crown Nurseries upwards of 30,000,000 plants ready for transplantation, mostly conifers. We are preparing to sow a large quantity of seeds this autumn. We are arranging for the training of disabled officers and soldiers as forest officers and woodmen, and the first of our classes opens at the Forest of Dean on the 3rd August. In this and in almost every other side of our activities we have proved the great advantage of woman labour. . . ."

Food Production.—Mr. Prothero next turned to the question of food production on farms. After remarking that this was the first opportunity he had ever had, although he had been some time now at the Board of Agriculture, of explaining to the House what the Board has been doing, he proceeded: "What, I think, the House would like to know is this: How much money has been spent, on what it has been spent, and what have you got for your money? . . . I propose to give you the information under seven heads: First of all, the head-quarter staff, then County Agricultural Executive Committees,

then labour, then ploughing, cultivation, machinery, supply of labour, horticultural operations, and then a few words as to miscellaneous expenses. . . .

" The harvest of 1916 proved a disappointment. Fertilisers, feeding stuffs, and implements were scarce. Something like two-thirds of the labour ordinarily employed on farms had been taken away from the farms which were previously, in many instances, under-manned, and farmers were quite unable, owing to the uncertainty as to the amount of labour which they could retain, to make plans for the cropping of the land. Meanwhile, the activity of the submarines, the stringency of our finance, and the strain on our tonnage, seemed to render it important that we should increase to the very utmost the output of food in this country. The materials most wanted were breadstuffs. Four-fifths of our requirements are normally imported, and corn being a bulkier cargo than wheat, is more difficult to carry in reduced tonnage. It was therefore decided, in December, 1916, to attempt what looked like an impossibility—to increase the area devoted to corn, roots, and potatoes. We knew that foodstuffs were likely to become extremely scarce, therefore we wanted to increase the area devoted to roots, and also to peas and beans, which I need hardly remind the House are, in farmers' language, included in the word 'corn.' We wanted to produce these crops for the human food, and also the animal food of the country.

" We opened this campaign on the 20th September, 1916, on a black winter day, and in what proved to be a protracted and severe winter. Though the general policy was dictated from Whitehall, it was felt that it must have agricultural opinion behind it, or it was doomed to failure. So it was decided that the movement itself should be in each district mainly controlled and directed by the farmers themselves, and for this purpose the best agency seemed to be the Local War Agricultural Committees which had been set up by Lord Selborne on the recommendation of the Milner Committee in 1915, and which were in some counties active, while in others they have had nothing but a nominal existence. It was through all these bodies that the campaign was opened on 20th September, and at that meeting, and in two circulars issued by the Board, dated 28th and 29th September, the immediate programme of increased tillage for 1917, and the further programme of increased tillage for 1918, with its motto of 'Back to the 'Seventies,' were sketched in outline. The formation of district sub-committees and of sections for the encouragement of allotments

and village pig-keeping was set forth ; and the prime necessity of getting a survey of the land in each county and of the area of grass land which could advantageously be brought under the plough, was insisted upon. The reduction of the area devoted to luxury crops, like mustard grown for seed, or flowers and bulbs, was pointed out and urged upon the Committee, and finally the promise was made to the Committee that they should have clerical and skilled assistance, that they should have furnished to them for each county a quota of produce, and that they should also have compulsory powers to enforce cultivation wherever it might be necessary. Early in January the Board transferred to the War Agricultural Committees most of their own compulsory powers. It required those War Agricultural Committees to act through Executive Committees, which were appointed according to the terms of the Order. Before the end of the month the Executive Committees were in existence with competent executive officers. The whole of the counties were grouped into 17 districts, subsequently increased to 21 ; in 15 out of the 17 districts Commissioners were appointed, and these instructed in their duties, among which was to forward a weekly report of progress. Before the end of the month one of the committees completed its survey. The first derelict farm dealt with was on 5th February, 1917. By the end of the month they were all actually at work stimulating cultivation and laying their plans for increased tillage.

The Food Production Department.—" Meanwhile, on the 1st January, the Board set up a Food Production Department. I think the House is probably aware that the Board of Agriculture had been for years something in the nature of an agricultural local government board—that is to say, its only duty had practically been to administer certain Acts of Parliament and to encourage agricultural research—and it had been divorced from any direct participation in the agricultural industry. It had nothing to do with prices, it had nothing to do with labour, it had nothing to do with fertilisers, it had nothing to do with feeding stuffs. Now it seemed to the Board that, inasmuch as farmers were placed in a position when they could no longer get the necessary requirements of their trade by themselves independently, we must pursue a new action, and so the subsequent history of this movement has been not a gradual loss by the Board of Agriculture of powers which it never possessed, but its acquisition of new powers in the face of Departments which were already strongly entrenched and

already in possession of those powers. I think it only right to make that explanation, because it has very often been thought that the Board of Agriculture gave up some right of fixing prices. It never had it. The right of fixing prices belonged to the Board of Trade, and the only maximum price that had been fixed in 1916 was fixed by the Board of Trade. So also with fertilisers and feeding stuffs—they belonged to the Board of Trade.

“ We set up this Food Production Department on 1st January, 1917, and we set up at once sections in it to deal with local organisation—that is to say, with the War Executive Committees—to deal with supplies, including fertilisers and seeds, to deal with horticultural work and allotments, and with labour, and with machinery. We collected an admirable staff of technical assistants from the colleges and institutes, and an advisory committee was set up, consisting mainly of farmers, who met for the first time, I think, on 19th January, 1917, and have sat since then continuously, meeting every fortnight. At the same time we established a woman's branch, exclusively run by women for women, to deal with whole-time and part-time workers, and we strengthened the county organisations. We also set up a credit system for farmers, for the purchase of the requisites of production, arranged through the joint stock banks. To meet the labour difficulties, or to help in meeting them, orders were placed for a large number of tractors with the Ministry of Munitions, steps were taken to discover the number of steam ploughing sets, and to obtain the return of the essential men to man them. We made arrangements with the War Office for the supply of agricultural companies formed of soldiers, for the supply of German prisoners, and for the hire of heavy horses with soldier drivers, and with the Home Office for conscientious objectors. That, however, never came to much.

“ The spirit of the agricultural community was excellent. They were willing to make great sacrifices in the interests of food production, but they were naturally reluctant to plough up their grass. Nobody, except in rare cases of potato land, is much disposed to plough up grass. In the first place, grass is in a way the sheet-anchor of their safety. Its profits are sure, the outlay is small, the labour bill is small, and also farmers have had 40 years' bitter experiences of corn prices, which had ruined thousands, and they were naturally, though prepared to make great sacrifices, not prepared to face such a slump in corn prices as would drive them to bankruptcy. It was in order to remove that initial difficulty that the Govern-

ment decided to guarantee minimum corn prices for a period of years, and the Prime Minister's speech on 23rd February, 1917, announced that policy. We were very late in the season, and we could do very little for 1917, comparatively speaking. But we did get, considering the time, a very considerable addition of land under crop. I think I am speaking within limits when I say something like 280,000 acres. At a time when the world's supply of food became seriously short, that extra supply helped the country very materially to turn an awkward corner, and the huge potato crop proved perfectly invaluable to the nation.

"The first edition, so to speak, of the Food Production Department was headed by officials of the Board. Their time was absorbed in conferences with the War Office and the Ministry of Food on a variety of topics, and whatever time remained—and work was often prolonged till midnight—was spent in organising the War Executive Committees and in installing the new Department into its new offices. But it became increasingly evident that if we were to grapple with this problem satisfactorily, we must have a chief at the head of it who was prepared to devote his whole time to perfecting and running the machine. That chief we were fortunate enough to find in Lord Lee, then the hon. Member for the Fareham Division, and chairman of the Bucks Executive Committee. In his hand the Food Production Department became a living, effective organisation. His organising ability and his energy, enthusiastically backed by a most loyal and able staff, filled in, as it were, all the details of the framework and clothed the skeleton with flesh and blood and muscle. It is very largely owing to him that the Food Production Department has been able to help so effectively the movement towards increased production, but while I want in the fullest possible way to acknowledge my debt to my colleagues in the Food Production Department, I do not, I need hardly say, desire in the remotest degree to evade my own personal and official responsibility. I met the Director-General in personal consultation three times every week, and once a week I presided at a conference of all the officials of the Food Production Department. . . .

The County Agricultural Executive Committees.—"I go on to the County Agricultural Executive Committees. There are 63 of these committees, and there are some 500 district sub-committees. Each of the executive committees is allowed expenses for office staff and funds for office management. These have formed themselves into sub-committees dealing

with labour, machinery, supplies, finance, and, in the last few weeks, threshing machines. Through the district committees the executive committees are in touch with every district. The counties, as I have explained, are grouped into 21 districts, each with a district commissioner, who is himself *ex officio* a member of all the executive committees within his district. It is to these War Executive Committees that the Board has delegated its powers, and it is through them that the Department acts. The members of these committees are, for the most part, men of business, dependent for their livelihood on their business. Yet on both the executive and district committees they have given their time, their skill, and their experience without any pay or reward. They are all of them unpaid. The tasks they have had to perform are extremely difficult, delicate, and invidious. I think they have faced them with a rare courage as a public duty in the national interest. Mistakes, of course, they have made. The enormous amount of work they have had to do would make it perfectly absurd to expect anything else. But I am convinced of this, that anybody who knows their work believes that their work has been done both ably and well, and the nation owes them a great debt of gratitude.

Survey of Agricultural Land.—"Their work has been very varied. I will only mention two points. One was the survey of the condition of agricultural land. The result of that has been that we know far more of the condition of agriculture in this country to-day than we have ever known in the history of agriculture. We have got a good record of the traditions of cultivation of the land. The other task to which I allude was the task of issuing notices for ploughing up grass and for specific acts of cultivation. Something like 100,000 notices have been issued by these committees. I think it speaks volumes for the patriotic feeling of both landowners and farmers that in only 372 cases was the Board asked to authorise proceedings for wilful failure or neglect to carry out those Orders. In the majority of these cases proceedings became unnecessary, and only 72 cases have come into Court, and in only one of those cases have we failed to get a conviction. But even if all the prosecutions which were authorised had resulted in proceedings it would have been something below one-third of 1 per cent. of the notices which were served, and the result of the work of the committees has been not only a great increase in the area of arable land, but a most substantial improvement in the general standard of farming throughout the country.

Drainage Schemes.—"I may, perhaps, add also that the drainage powers conferred by the Board on these committees have been used with very great success. We have in hand schemes, some of which are already completed and some are approaching completion, by which something like 120,000 acres of land will be brought into profitable cultivation. I mean by drainage not pipe drainage, but the drainage of surface water.

Now the expenditure on these local organisations for the 15 months ending 31st March, 1918, falls under two heads. First, there are the administrative expenses for the 63 executive committees and 500 district committees. Members have given their services unpaid. The total sum is £176,038. The Grants for farming and drainage and other operations, the bulk of the expenditure being recoverable, have been £146,522, making a total expenditure on the local organisations for those 15 months of £322,560.

Labour.—"I should like to make it quite clear that no labour is given to the farmer. The farmer pays in every instance the local wages rates of the district, except in one instance. He pays 5*d.* an hour to the German prisoners, which is slightly below the rate for agricultural labour. Of course, agricultural labour has been throughout the very great difficulty with which we have had to contend. Agricultural labour is so much less mechanical than other labour that it is far more difficult to deal with it, either by dilution or substitution. Nothing can replace to the farmer the man who knows the land on which he has worked all his life probably, and who knows not only what he has got to do, but how he has got to do it. And it is for this reason that the Board has throughout endeavoured to secure to the farmer men indispensable for cultivation and so far as the exigencies of the military situation would allow, to make sure of the number of men which he would be able to command. It is the uncertainty on this point that almost paralyses his efforts. From June, 1917, to April, 1918, when the Royal Proclamation was issued, this difficulty was satisfactorily met. The Cabinet decision during that period remained in force, that a man who was on a farm on the 1st June, 1917, and whole-time employed on farm work of national importance, could not be posted without the consent of the War Executive Committee. That secured us our labour for that time, but even during that period the shortage was severe.

"In quantity, of course, the loss of labour was mitigated, but in quality the loss could not be made good. The new labour was, for the most part, unskilled and inexperienced, and it is quite obvious that dealing with labour of that kind

increases expenses very largely. Less work is done, and the work that is done is less efficiently done, and at no time during the whole of this effort was the Department able to secure what it had put forward as its minimum requirements, and which were promised by the Government. We had to do the best we could. Naturally, the supply of this outside labour has varied enormously in these 15 months. I could give it month by month, but I do not know it would be worth doing. But I may give it at the beginning of the financial year—that is to say, on 1st April, 1917, and at the end of March, 1918. On 1st April, 1917, when we were in the full swing of our ploughing operations, we had approximately 36,000 soldiers including ploughmen, who had been returned from the front for that special purpose—men of the Home Defence Force and Agricultural Companies, and 830 German prisoners and interned aliens. At the end of March, 1918, we had 61,000 soldiers and 10,200 German prisoners and interned aliens.

Woman Labour.—"The other supply of labour is woman labour. As I have said, we created this branch early in January. It has been run throughout by women, and since the food production campaign began the number of women on the land has been increased from something like 91,000 to over 300,000, that is to say, whole-time and part-time workers. The local organisation in each county consists of a Women's War Agricultural Committee, of district sub-committees, an outfit officer who distributes the outfits, and a village registrar. All these are volunteers and unpaid. Besides this, we have a paid official staff of one organising secretary in each county, and for all the counties of England and Wales 17 travelling inspectors. The House may think that organisation is elaborate. May I put one reason why we could hardly make it less? The Board undertakes a very serious responsibility if it sends young women on to the land in a remote country district without making tolerably certain—in fact, without making quite certain—that they shall have a friend within reach to whom they can go in any difficulty. This is the object of this rather elaborate organisation. Moreover, the work of the local organisation includes the inspection of billeting accommodation—a very important point—the introduction of the supply of labour to farmers often averse to a novelty, the formation of groups of part-time workers under skilled leaders, so that in the case of each woman who can only serve half-time they can make up the whole-time work from a group of women, and the collection of seasonal workers in large numbers.

" Besides the village women included in the 300,000, there are what we call the Land Army. These are women who have undertaken to work on the land and to go wherever they are sent. They are recruited from all classes of the women of this country. I hope the House appreciates the difficulties with which we are faced in respect of these, what I may call mobile women. The agriculturist cannot compete with other industries in respect of wages. Physically the work is hard. It is monotonous. It is carried on out-of-doors in all conditions of weather, and in respect of accommodation it implies real privation and real hardship. These facts have never been concealed ; yet we have got, or we had at the end of the financial year—the numbers are larger now—11,000 women who had patriotically responded to the appeal. That appeal is strengthened, I think, by the fact that they have to make sacrifices, and have to endure privations, which to some extent are comparable to those of their friends and relations at the front. Certain inducements we do offer. We give a month's training free. I know you cannot call it real training, it is more to get their muscles into something like condition, to give them something approaching the condition required for agricultural work. We maintain them in depots between the terms of training and of employment. For instance, we get them trained and it may be some weeks before they get employment. Again, they may leave one employment and they may have to be kept before they get another engagement. We keep them during these periods at depots. We provide them with an outfit. I should like to say a word or two about the outfit. It is not a decoration. It is absolutely essential for them in which to do the work they are called upon to do. It happens, I think, to be pleasing to the eye, but that is owing to the fact that it was chosen by women for women. I cannot claim any credit for that. We do, however, give them a certain outfit and we renew it half-yearly. The total expenditure upon the women's branch during the period of 15 months has been £230,273. The principal item is for this outfit, which comes to £130,037. . . . Part of this payment includes boots for the village women. These find it very difficult to get boots at all. We found this difficulty so great that we said we would get them for them if they paid for them, and the Treasury allowed us to make them a grant of 5s. towards the cost of these boots. Some part of that expenditure is capital expenditure on the outfit, besides depots and furnishing. But I can give the amount we actually received up to 31st March, 1918. It was £48,440. . . .

Ploughing and Cultivation.—"I now pass to the fourth head, ploughing and cultivation. In spite of every effort we could make to find labour, the shortage of manual labour was most acute, and we had to provide mechanical and other assistance. Once again I should like to remind the House that without the help of the Board the farmers could not have helped themselves. The sources of supply were cut off from them, and the richest and most independent of them could not buy English-made machinery nor secure a supply of motor fuel, nor purchase implements or harness. Therefore, we had to do for the farmer what the farmers, I daresay, would have done much more easily for themselves, but which they could not. In the case of steam tackle, there were, in January, 1917, 510 sets. Of these only 250 were able to work, because the owners could not get them repaired, or had lost their skilled men. The Department was able, by the summer of 1917, to put 210 of these broken-down steam-tackle sets into operation, and to get back from the Army 300 skilled men to drive them. The remaining 40 sets were obsolete, or beyond repair. Since then we have been hoping for 90 additional steam-tackle sets for the ploughing season of 1918. Of course, steam tackle and steam cultivation remain on heavy land by far and away the best implement for ploughing. We must, therefore, make every effort in that direction.

Horse-drawn Implements.—"Take horse-drawn implements. We arranged with the War Office for facilities for farmers to hire horses and soldier drivers. We also obtained the sanction of the Treasury to purchase a number of horses, and we made the necessary arrangements. During this period we have placed 9,749 horses at the disposal of farmers on hire. We have had going 36 ploughing schools in the country. We have trained a very large number of ploughmen with the horses. We have also had to provide the necessary ploughmen. We have provided horse-drawn implements. We have consigned upwards of 18,000 binders, ploughs, drills, harrows, presses and rollers, and every other kind of implement to executive committees for their own use or for hire out to the farmers.

Threshing Tackle.—"As to threshing tackle, we have had very great difficulty in increasing the supply beyond the increased supply provided last year. I am glad to say, however, that I think we shall have something like 350 additional threshing machines available for the coming harvest. The County Executive Committees have, at the request of the Department, appointed sub-committees, whose duties are to

get the threshing tackle into repair, and find the necessary labour to organise and use the tackle to the very best advantage, so I hope we shall be able to cope with the demand.

"The total expenditure under the head of steam tackle, horses, and horse-drawn implements was £319,269. The greater part of this expenditure, of course, is recoverable.

Tractors.—"A great development has been effected by the Department in the use of tractors for ploughing and cultivation. Many difficulties were encountered. Supplies from overseas came in but were liable to interruption. The English makers' works were closed, and the farmers looked with great suspicion upon the tractors as novelties. They were, however, only too pleased to put them into use; at all events, in some parts of the country a very difficult task. But, as I say, they were pleased to obtain the machines in the great emergency in April and May, 1917. We had a fleet of some 666 tractors, some of which we owned and some of which we hired. I have no doubt whatever that much of the tractor ploughing done at that period was costly and inefficient, but there was no other way to get the land up. We had to do the best in the very great emergency, and all due care was exercised, and I have no doubt the best possible results obtained. We stand in a different position now. At the beginning of the financial year, that is, in April, 1917, we had 660 tractors, some hired and some Government-owned. At the end of the financial year, 1918, there were 3,000 Government tractors at work, and it may be of interest to know that the tractors dealt with, I think 611,000 acres, and that the steam-tackle sets dealt with something like 1,000,000 acres. We have had to establish a base depot for tractors at Willesden. The reason for that is that we wanted to avoid the duplication of supplies. If we had supplied each executive committee with spare parts and fuel we should have had to supply a very much larger quantity than by having the base supply, and by having this the committees have been provided, and great economy effected. We have had ploughing centres where we have trained 6,000 men for ploughing, as well as a very large number of women, who are very successful with the lighter type of tractor. The schools, having done their work, are now closed. . . .

"The working expenses (including all salaries, wages, bonuses—there is a bonus upon ploughing above a certain quantity in a certain time—fuel, spare parts, repairs, insurances under the National Health and Workmen's Compensation Acts, a portion of the expenses of the head office and the

executive committee) amount per unit of ten tractors—that is the way in which we handle it—to £136 10s. a week. Each tractor is estimated to plough 10 acres a week, and each unit, therefore, ploughs 100 acres a week. At the minimum charge of £1 per acre there is a weekly earning of £100, or deducting $7\frac{1}{2}$ per cent. for bad debts, of £92 10s., as against the working expenses of £136 10s. If you bring these figures down on an acreage basis the cost is 27s. 4d. an acre, against the net earning of 18s. 6d. per acre. If you put depreciation at 20 per cent. per year on all the tractors, the ploughs, and other equipment, it would add £13 10s. to the weekly cost, so that the weekly cost would be £150. . . . The £150 is not wholly cost to the State, as I was explaining, because two-thirds is recovered by the charges which are made, and with regard to the £150 you must remember that it includes depreciation on capital expenditure. The total amount expended on the purchase of the necessary implements and equipment from 1st April, 1917, to 31st March, 1918, was £895,685. The working expenses for the same period were £700,095, making a total of £1,595,780.

Supplies.—Fertilisers.—" I pass on to the fifth head, namely, supplies. In dealing with the supplies, fertilisers are, of course, our principal difficulty. The manufacture of fertilisers rests with the Ministry of Munitions, who have always helped us in the greatest possible way. Since March, 1917, distribution has rested with the Department; before that time it belonged to the Ministry of Food. We have arranged a flat rate of railway delivery so that the farmers of the United Kingdom, however distant, get their sulphate of ammonia exactly at the same rate. One great difficulty we had to deal with was that the works became choked and impeded as the sulphate of ammonia accumulated, and the relief which the makers of sulphate of ammonia found was by exporting it. We had to stop the export, and at the same time provide some means by which the congestion could be met. We arranged a sliding scale of payments, by which merchants were encouraged to order early, and the price was raised towards the end of the fertiliser season. This worked with remarkable success. The fertilisers have gone off quite easily, and there has been no congestion. Another thing we have done is to take in hand the railway distribution of fertilisers. Every manufacturer is allowed to supply his old customers within a 5s. railway radius. Beyond that he has to come to the Board for a special licence, and we exercise that licence with due regard to railway

transport and the facilities of supply wherever the manufacturer proposes to send the fertilisers to. We have consulted the Railway Executive over this scheme, and they sanctioned and approved it.

" We are dealing on the whole with superphosphate, sulphate of ammonia, and basic slag to the extent of 1,100,000 tons, and we hope we shall effect a saving of something like 20,000,000 ton-miles by this method of licensing, which is a matter of great importance. We have also managed to increase the supply of sulphate of ammonia very considerably. The amount of sulphate of ammonia consumed by the end of the fertiliser year of 1916 was something like 65,000 tons; at the end of this fertiliser year, namely, the 31st May, 1918, we had used 238,000 tons, and we could have sold a great deal more if we had been able to do so. We increased the amount of basic slag very greatly. We hope in this coming fertiliser year to have an increase of between 300,900 and 350,000 tons. We have prevented compound fertiliser manufacturers utilising superphosphates and sulphate of ammonia at a higher price than those ingredients sold for. We oblige them now to give an analysis according to the fertiliser constituents of the compound. It is a thing for which agriculturists have been clamouring for years.

" Superphosphates, of course, we have great difficulty in dealing with, because the ingredients are from abroad, and I think I ought quite frankly to confess that we made one bad blunder. We wanted superphosphates very badly in March, 1917. We wanted to get it on the land immediately. We heard of a cargo of superphosphates at Lisbon. We bought them. We thought we had arranged Blue Book rates. We did not get Blue Book rates; we got the ordinary freights, and we found we had landed with a very considerable loss—a loss of £28,000, or something in that region. But we got the superphosphates on the land, and if you put into the account what is calculated to be the ordinary increase of 1 cwt. of superphosphates, which is 4 bush. to the acre, I think we may possibly have recouped the loss of that unfortunate blunder.

Seeds.—" In the case of seeds we had to do what we very much dislike doing, and that was going into trade at certain times. We tried our utmost to do everything through the seed merchants, who most loyally co-operated, but on occasions we have had to buy seed wheat and seed oats—seed wheat, for instance, for the spring operations of March, 1917, seed oats for the last winter, because these supplies were very scarce. We have, in each case, recouped ourselves the outlay, but we

never wanted to go in for the seed trade, and, as I have said, have always tried to do everything through the trade.

"As to *seed potatoes*, nobody who remembers the bungle and confusion which occurred in regard to potatoes in 1917 will fail to understand that in carrying out the large orders which we had to do on that occasion for the small allotment-holders it was easy to make a blunder. We had to deal with £200,000 worth of potatoes for seed. We had contracted with the allotment-holders to sell them at what was then the seed-potato price, but after many fluctuations . . . we ultimately fixed it at a much higher price than we had contracted to sell them to the holders. We had to decide whether we would charge the allotment-holders or stand the loss ourselves. We decided to stand the loss ourselves, and it came to something like £5,000. I think on a transaction of £200,000 to lose only something like 2½ per cent. was not in the circumstances a very heavy expense.

"There are other points in the supplies which we have had to deal with. We have got a considerable supply of potash coming forward. We have provided for binding twine. We have had to provide seeds for allotments. That is the greatest difficulty in the development of allotments, and in order to provide the seeds we had to get the seed merchants to consent to limit their export trade until we knew that our home wants were met. They did that very loyally, and we had to provide ourselves with seed. Then there is the question of spraying. We had to provide over 6,000 potato-spraying machines, all of which were sold very rapidly to the farmers or to the allotment-holders. I think there were 6,746 machines, which were sold at cost price or at very little more to the allotment-holders. We have had many demonstrations in the use of spraying, and I hope that it has been pretty general this year. The total charges for the supply division were £437,947, out of which we expect to recover £372,177, and we have recovered £282,955.

Horticulture.—"There remains the horticultural side. It has been most carefully organised to encourage the allotment-holders and small cultivators. We have horticultural representatives in 918 districts, and it is mainly owing to their efforts that we have formed 741 food-production societies. We have also given instruction to the allotment-holders through a panel of gardeners, numbering over 2,000, who have given their services without payment, and our inspectors have encouraged the growth of allotments. Some of these returns as to the number of allotments may be of interest. In county boroughs the increase of allotments is 279 per cent. In 125 towns from

which we have received returns the increase is 131 per cent. In 499 urban districts the increase is 164 per cent. Altogether, whereas the number of pre-war allotments was 570,000, it is now over 1,400,000. We have also taken in hand a very considerable amount of work in the preservation of fruit and vegetables. We set going a very considerable organisation for that purpose at the request of Lord Devonport, then the Food Controller, but in November the Food Controller demanded our organisation back again. We were not unwilling to give it up, and we were only too glad to be able to hand him over a going concern. We continue to look after some fruit and vegetable methods of preservation, such as canning and bottling, and whereas the number of bottles generally provided is something like 600,000, we have now obtained and are in course of distributing something like 6,000,000 bottles. That will give some idea of the extent to which the preservation of fruit and vegetables has been carried. We have also provided for the making of agricultural baskets, and I hope that something like 1,000,000 baskets—a matter of great interest in all fruit and vegetable work—will have been provided. Altogether the expenses of the horticultural branch have been £109,403, of which a large part, of course, is recoverable. . . .

Miscellaneous.—"The last item is 'Miscellaneous.' There are not really so many items under that head as might be expected in such a lengthy list of expenditure. The total expenditure under 'Miscellaneous' is £4,934.

Seed-testing Station.—The most important item is that of a seed-testing station. We set up a seed-testing station at which seeds can be tested for purity and germination. Hitherto it may surprise the Committee to know that in England, although it is the greatest emporium for seeds in the world, we have sold our seeds abroad with a foreign certificate as to purity and germination. The seed-testing station was started on a small war scale, but already it promises to become self-supporting.

Results.—The total expenditure under all those heads is £3,133,003. Out of this we expect to recover £1,452,940, leaving an expenditure—and you must remember that a great part of this is capital expenditure—of £1,680,063. Of the recoverable amount, we have already, up to 31st March, 1918, recovered £602,985. Therefore, the expenditure which may be charged against the Food Production Department is £1,680,063. A great part of that, something like £1,200,000, is capital expenditure, and if you spread it over a period of four years obviously it becomes a much smaller sum. That

is the amount which has been spent and how it has been spent. The House would like to know what it has got for the money. After all, that is the most important point.

"We have been charged very often with dealing only with what we have done as a matter of acres. People say to us, 'Why do not you deal with it from the point of view of the produce?' Surely that is a most unreasonable proposition! How can we deal with what we have done as a matter of produce until the wheat, for instance, has gone through the thrashing machine? You do not know till then. All that we can tell is that as a result of this expenditure, instead of a considerable decline such as might have been expected in 1916, we have increased the arable area of the country by 2,142,000 acres. It has been cropped in this way: We have an increase of wheat of 752,000 acres, or 39 per cent., which is the highest acreage of wheat recorded since 1882. We have increased barley by 158,000 acres, or 11 per cent. We have increased oats by 735,000 acres, or 35 per cent., showing the highest on record by 23 per cent. We have not neglected the crops for live stock, because we have increased the acreage of rye, peas, beans, etc., by 280,000 acres, or 69 per cent. We have increased potatoes by 217,000 acres, or 50 per cent., giving the highest on record by 27 per cent.

"It does not stop at that. This movement has spread to Scotland and Ireland. We have the highest acreage under corn crops in the United Kingdom that has ever been recorded in the history of British agriculture. Nor has it stopped there. I will not say that the movement has been imitated, but it has set an example to France, to Italy, and to Greece. Our methods have been studied in all those countries, and in Italy and Greece they have been largely adopted, with the result that Greece hopes to become self-supporting with the harvest of 1918. Of course, you cannot tell what the harvest is going to be, but, subject to it being an average harvest, the position of the Allied countries as regards food is vastly better than it was in 1917 or 1916, and the relief to our tonnage in not having supplies from America by reason of the food supplies that are now grown here and in the Allied countries is very great and likely to be of material assistance to us.

Ploughing up of Grass.—"I should have liked to have gone further. I should have liked, if we had had the labour, to have ploughed up more land. I am afraid that in this matter of ploughing I am one of those who stand midway between two schools. There is one school which wishes to plough up nothing

and there is another school which wishes to plough up everything, and, like a member of a Coalition Government, I suppose I have no friends because I stand between the two ; but I am convinced that with our existing supply of labour we could not safely carry out the programme of further ploughing which we had in mind. We had designed to increase still further the arable area, as we might possibly have done given the labour, with a view, some three or four years hence, of approaching the time when we might be self-supporting. I have said that it is impossible to carry out that programme, but we hold it before us as an ideal, and if ever labour is materially and substantially improved and secured we should be prepared to undertake some portion of it, but for the present we have suspended the issue of all ploughing-up notices. We have, of course, to deal with those notices which are already out, and as to those we have adopted the position that in each case they are to be reconsidered on their merits with regard to the supply of labour and the changed conditions which may have taken place. If no change has taken place in the condition of the farm which would prevent the notices being carried out, they will be carried out for this reason : The Orders which have been held in abeyance are Orders given out for the most part some months ago, and they were allowed to delay carrying them out in order, for instance, that they might get their hay harvest in. I feel that it would be so unjust to suspend them altogether if the man is still able to carry them out, and this would create an ill-feeling amongst those farmers who carried the Order out at once.

The Farmers' Sacrifices.—"In conclusion, I should like to say a word about the splendid support given by the farmers themselves. I do not think the public really understand what sacrifices the farmer has made. I am not talking about the man who grows some exceptional crops, but of the fixed arable farms, which are the principal stand-by in this country. I do not believe people realise what sacrifices of money profits those men make. They accepted the new principle which we tried to put before them. It is not now a question of what is going to pay them best, but it is a question of what will produce the most food, and they have most loyally met my appeal. Looking at the performance, which is, after all, not the performance of a Department or of the Board, but the performance of a great number of small men—after all, the vast majority of these farmers come under that definition—it is an effort to meet a great national emergency, and I regard the farmers' performance as one of the great achievements of the War."

THE IMPROVEMENT OF LIVE STOCK IN ENGLAND AND WALES.*

REPORT FOR THE YEAR 1917-1918.

THE Live Stock Scheme has now been in operation for four years, but its objects and methods are still so little known, except in districts in which it is in actual operation, that it may be well to explain very briefly that its chief aim is to improve what may be termed the commercial stock of the country by educating farmers and others to the value of using sound pedigree sires of good type and conformation and of keeping accurate milk records of dairy cows. To this end financial assistance of the following amounts is given annually to societies which are formed to promote the objects of the Scheme :—

Heavy Horse Grants.—A grant not exceeding £80 (£40 direct and £40 for assisted nominations) in respect of each stallion travelled by a society.

Bull Grants.—A grant of £15 in respect of each bull provided by a society, and of £12 if provided by an individual.

Boar Grants.—A grant of £3 in respect of each boar.

Milk Recording Grants.—A grant at the rate of £2 10s. per herd but not exceeding half the annual expenses of a society.

The period covered by this Report (1st April, 1917—31st March, 1918) is the fourth year of the operation of the Scheme, which has, therefore, only one more year to run to complete the quinquennial period allotted to it when it was first introduced and financed from the Development Fund. In estimating the results obtained it must be borne in mind that normal development of the scheme has been affected, except during a few months at the outset, by the increasingly adverse conditions arising out of the War. The withdrawal from civil life of so many of the young farmers and farmers' sons, who have answered the Nation's call to arms so readily, has considerably reduced the number of progressive agriculturists to whom the Scheme was most likely to appeal, and from whom much support was expected. Shortage of labour, rise in the price of sires, scarcity and increased cost of feeding stuffs, and uncertainty as to beef and milk prices, have also been factors which have militated against its full development.

* Owing to the War this article replaces the Annual Report on the Live Stock Scheme, which will not, therefore, be issued separately.

But if the War has tended to retard the development of the Scheme it has also demonstrated very clearly the importance of grading up and raising the standard of the ordinary farm stock of the country, so as to secure as large an increase as possible in the home supply of meat and dairy produce. What was long felt to be desirable the War has made urgent, and when hostilities cease, there will be, without doubt, a greater demand than ever, from both home and foreign markets, for a supply of cattle, especially of pedigree animals, to replenish the world stocks that have been depleted by the War.

In live-stock breeding quality and quantity are closely related. The better bred the animal the more likely is it to be a profitable investment both to the individual owner and to the nation, as a greater weight of beef or yield of milk can be obtained in less time and at less cost from a well-bred steer or cow than from a badly-bred one. Regard must be paid also to heredity if any degree of certainty is to be secured in successfully breeding either for milk or for beef or for both. These are not theories, but well established facts which have been proved by years of practical experience. Pedigree breeders are well aware of them, and the excellence of their breeds is testimony to the value of pedigree and of selective mating. It must be admitted, however, that farmers, however cognisant they may be of these fundamental laws of breeding, in a very large number of cases ignore them in their practice. They shrink from the immediate outlay and exercise little, if any, care in the selection of sires, and the results of their haphazard methods are only too evident from the large numbers of low-grade stock, unthrifty doers and poor milkers that are to be found in most parts of the country.

The Live Stock Scheme was initiated, therefore, in order to educate the ignorant breeders to the use and value of pure-bred sires and to the commercial advantages of breeding from parents, whose types and characteristics are known and have been fixed by a careful breeding, and which are more likely, therefore, to be reproduced in their progeny.

Inasmuch as the Scheme has been in operation for only four years any marked improvement in the stock of the country cannot be expected. It must be remembered that so far as horses and cattle are concerned few, if any, animals will have been bred under the Scheme during the five years ending 31st March, 1919, which contain more than one cross of a subsidised sire, whereas several crosses are essential to grade up inferior stock and to bring home to breeders the pecuniary and other

advantages of using good sires, and of exercising care in mating, feeding and rearing.

In this connection the work of the Live Stock Officers may be mentioned. They have got into close touch with large numbers of farmers in their provinces and have been successful in stimulating considerable interest in the Scheme, both direct and indirect, and have been able to foster healthy rivalry amongst breeders to possess better quality bulls and stock generally than have been hitherto kept by them.

The assistance and co-operation of the Provincial and Live Stock Committees have been of considerable value in the administration of the Scheme, and the Board are much indebted to the members for their help. It is satisfactory to be able to report that the Board received during the year under review representations from all the Provincial Committees bearing testimony to the direct and indirect value of the Scheme and urging the need of its continuance.

The Board fully realise that four or five years are quite inadequate to secure any material improvement in the stock of the country. Some progress is already visible, however, as a result of the Scheme, and it is something accomplished to have evoked interest, and to have overcome in some degree the indifference and prejudice of the ignorant and careless breeder which constitute so serious a barrier to improvement and development. The Scheme, which the Development Commissioners agreed to finance for the five-year period ending 31st March, 1919, may be said to have justified its existence, and though some amendment of it after the above-mentioned date may be considered desirable the Board are satisfied that it is sound in principle and effective in operation, and they intend to continue it, and, when opportunity offers, to develop and extend its scope.

The amount available for the purpose of awarding grants during the year under review was allocated as follows :—

Boars	£
Bulls	1,348
Heavy Horses	12,727
Milk	6,235
								1,500
Total	£21,810

The following table shows the progress made by the Scheme during the four years it has been in existence, and in view of the prevailing conditions the progress made during the year 1917-18 was not unsatisfactory :—

Year (1st April to 31st March).	Boars.			Bulls.			Horses.		Milk Recording.	
	Societies.	Individuals.	Boars.	Societies.	Individuals.	Bulls.	Societies.	Stallions.	Societies.	Cows.
1914-15 ..	100	Nil	107	285	26	370	65	72	16	7,331
1915-16 ..	180	Nil	193	489	28	633	88*	97*	20	9,811
1916-17 ..	186	15	216	543	15	659	93*	108*	22	12,950
1917-18 ..	172	92	264	578	14	710	94*	110*	25	14,404

* Excluding the Cumberland and Westmorland Heavy Horse Society, formed in 1915-16.

Grants for Boars.—In many districts considerable difficulty is experienced in forming Boar Societies, and it has been urged that the amount (£3) of the grant made in respect of a boar is not sufficiently large to encourage farmers to pay the present high price of a suitable sire, and that boar owners prefer to be free from society regulations.

In view of the limited funds at their disposal the Board have not been able to increase the amount of the grant, but in order to encourage the use of any good sire that may be available, the award of grants has been made during the year to individual owners who agree to place their boars at the service of their neighbours. A substantial increase in the number of boars located has resulted. In some districts the grants available have been freely taken up, and some small farmers are beginning to appreciate the advantage of breeding from good pedigree boars, and have purchased pedigree gilts for mating with them. That this will be attended with satisfactory results is shown by a recent sale by a village shoemaker of a Gloucester Old Spots boar for 65 guineas. Unfortunately, however, the importance of a good boar is not so generally realised as it ought to be if it were remembered that a stud boar is often the sire of 500 to 800 pigs in a year.

The number of boars subsidised and placed out during the year was 264 as compared with 216 in 1916-17. Of the 264 boars located, 110 were Large White, 76 Large Black, 20 Gloucester Old Spots, 10 Berkshire, 17 Lincoln Curly Coat, 15 Middle White, 13 Cumberland, and 3 Large White Ulster. The average price was £9 6s. 8d. per boar, and the highest sum paid was £29 8s. for a Gloucester Old Spots. The service fees varied from 2s. to 7s. 6d.

Grants for Bulls.—Reference has been made already to the fact that marked improvement cannot be looked for, as the

Scheme has been in operation for only four years ; but it is encouraging to be able to report that owners of heifer calves that have been sired by subsidised bulls rarely part with them, and if they do so they have no difficulty in finding ready purchasers. The best of the bull calves are also retained for use as sires, and those that are sold for rearing make good prices. Many members of societies that have been in existence for three or four years are learning the value of pedigree, and they begin to realise that well-bred stock costs no more to feed than mongrel stock, matures better, and is a far more remunerative investment when the time comes to sell.

The societies and individual owners who have purchased bulls under the Scheme often hesitated at first to pay more than £30 for a sire, but many of them are now quite willing to invest £60 to £100 in an approved sire. The visits paid by prospective purchasers to private pedigree herds and public sales of such animals have afforded valuable object lessons in the value of scientific breeding and rearing, and have encouraged the acquisition not only of pedigree sires but of registered female animals as well. Many members, too, are keeping careful record of the crosses by pure-bred sires so that the progeny in years to come may be eligible for entry in the Herd Book of its breed. This, again, is a true index of the educational value of the Scheme.

It must not be imagined, however, that this progressive attitude is general throughout the country, as the beneficial effects of the Scheme have not permeated any distance outside the areas in which it operates, and there are still large numbers of stock owners who are indifferent as to the class of sire used by them provided its services are cheap and to be obtained without trouble. There is no need to labour this point beyond referring to the operation of the Calf Orders, which have furnished all too convincing evidence of the large number of calves produced annually, especially in some dairying districts, which are of such inferior quality or so unthrifty or ill-developed as to be quite unfit for rearing for beef or milk purposes. This condition of things is a disgrace to the stock-breeding industry of the country, but it is hoped that a continuance of the Live Stock Scheme may gradually secure a considerable measure of improvement.

As was the case last year the bull section of the Scheme has progressed notwithstanding the scarcity of good bulls at moderate prices, and the societies, with few exceptions, have continued to show keenness in the selection of their sires, and as

occasion arose for the substitution of a new bull every effort has been made to maintain and, if possible, to raise the standard of the sire. Numerous instances have been reported of subsidised bulls making high prices when sold abroad, and one society had two bulls which when purchased for their use cost £50 and £60. respectively, and when subsequently disposed of in the Argentine made £523 and £436.

The number of bulls located at the close of the year 1917-18 was 710, as compared with 659 in 1916-17. Of these 696 were provided by 578 societies, and the remainder by 14 individuals: 528 were located in England and 182 in Wales. The number of bulls actually purchased and owned by societies was 69, the other 627 being hired by societies from the owners.

The average prices paid for bulls were as follows: £54 18s. 9d. for Shorthorns; £52 18s. 11d. for South Devons; £52 9s. 2d. for Devons; £51 10s. 9d. for Lincoln Reds; £50 13s. 5d. for Herefords. and £37 6s. 6d. for Welsh Blacks. The highest price paid was £157 10s. for a Hereford. The service fees varied from 2s. 6d. to 10s. 6d.

Of the bulls located, 461 were Shorthorn, 73 Hereford, 64 Lincoln Red, 51 Devon, 38 Welsh Black, 13 South Devon, 2 Aberdeen Angus, 3 Guernsey, 3 Jersey and 2 Sussex.

Grants for Heavy Horses.—This section of the Scheme continues to be well supported, but it cannot be further developed until further funds are available for the purpose. It is satisfactory to be able to record that several of the societies which were formed four years ago. and started with one stallion, now arrange to travel two or three, and in one case four sires. Hiring fees have risen, but useful sound sires can still be had for £250-£300 the season, and they are of sufficiently high standard to encourage many members to purchase pedigree mares for mating with them. A few of the more progressive societies under the Scheme now hire stallions which are not subsidised, as they are travelled at fees exceeding the maximum (£3 3s.) authorised by the Board. Such development is good testimony to the educational value of the Scheme, and it is hoped that it will soon be the general rule and not the exception for societies to travel two grades of sires, one for the service of pedigree or high-class mares at four or more guineas, and the other for lower-grade mares at a fee of £2 10s. to £3 3s.

The "payment by results" system of hiring stallions appears to be growing in favour. It is certainly sound in principle and advantageous to mare owners, and also to owners of stallions that are good getters.

The number of subsidised societies during the year was 94 with 110 stallions, as compared with 93 societies with 108 stallions in 1916. The number of mares served by the 110 stallions was 10,556, an average of 96 per stallion. Assisted nominations (*i.e.*, payments not exceeding one-half the normal service fee) were paid by the Board in respect of 2,151 of the above mares. These figures do not include the 328 mares in favour of which assisted nominations were issued by the Cumberland and Westmorland Heavy Horse Society for service by 40 selected stallions.

The average hiring fee of the stallions was £258, and the average service fee charged was £2 16s. as compared with £244 and £2 11s., respectively, in the previous year.

Milk Recording Societies.*—The present price of milk as compared with the pre-war price accentuates the difference between a good and an indifferent dairy cow as a source of revenue. With milk at 1s. 6d. a gal. the gross income from an 800-gal. cow is £60 a year, whereas it is only £30 from a 400-gal. animal—and there are many of the latter in the dairy herds of the country.

The yields of cows belonging to members of milk recording societies subsidised by the Board show a wide variation. Comparing the average yields of cows that have been in herds for a full year the returns show the highest average yield of a society to be 7,342 lb., and the lowest 4,564 lb—a difference of 271 gal., or of £20 in cash per cow a year, between the value of the produce from the herds of the best and worst of the societies.

Facts like these should convince dairy farmers of the importance of keeping accurate and checked records of the yields of their cows, so that they may be able to ascertain with certainty the annual cash-producing value of their stock-in-trade, and to discard the unprofitable animals.

Under the Board's Scheme milk yields are checked by recorders who pay surprise visits not less frequently than once in six weeks, and the commercial advantage of this independent supervision and checking is of the greatest value to dairy farmers—it goes a long way towards preventing errors arising from mistakes or carelessness on the part of the milkers, or other persons who are primarily responsible for taking the records, and it furnishes a guarantee—so far as one is possible—of the accuracy of the yields.

* See also Leaflet No. 146, to be obtained post free on application.

In course of time it is hoped that a farmer, when he buys a dairy cow, will insist on having a guarantee of her milk-producing powers, *i.e.*, a certified record of her annual yield. He requires a guarantee of the horse-power of a steam or oil engine before he purchases it, and as he cannot form any reliable estimate from the appearance of a cow of her capacity as a milk producer, it seems only reasonable to require the vendor to produce evidence as to this essential qualification.

Having made arrangements for determining the annual milk yield of his herd the next step for the farmer to take, if he is to carry on his business on commercial lines, is to ascertain the cost of producing the milk, and for this purpose provision is made by the Board in their Regulations for assistance and advice to be given by Live Stock Officers on questions relating to economic feeding and rations.

Milk recording is in its infancy in this country. It is an innovation, and as such is regarded with suspicion by many farmers. Its advantages are not immediately apparent, but the little extra labour and the small cost it involves are repaid many times over by the results obtained. In districts, however, where Milk Recording Societies have been in operation for two or three years, it is evident that many of the members are beginning to realise the value of taking records and of using a bull of milking strain. As evidence of this a Live Stock Officer recently reported that he accompanied eight members of societies in his province to purchase bulls for use in their herds, and the sires selected cost 310, 210, 185, 166, 155, 140, 133 and 120 guineas respectively. Another society consisting of 36 members has agreed that at the close of the present milk-recording year its members will use none but pedigree bulls in their herds.

These examples indicate satisfactory development and improvement, and, notwithstanding the adverse conditions now prevailing, the number of societies during the year under review increased from 22 to 25 with 503 members owning 555 herds and 14,404 cows. The number of certificates issued was 2,189 as compared with 834 in the previous year. The highest yield certified was one of 19,646 lb., and the cow with this extraordinary record was recently sold for 3,500 guineas.

Dairy Register.—An important development of the Milk Recording Scheme is the issue of a Dairy Register by the Board. The first volume has been published recently, and contains particulars and records of cows which yielded during the year ending 30th September last not less than

8,000 lb. of milk, and in respect of which certificates have been issued by the Board. There are 572 entries in the first volume, and the number of cows of the various breeds or types are as follows: 396 Shorthorn, 60 Lincoln Red, 58 British Friesian, 45 Crossbred, 10 Red Poll, and 3 of other breeds.

In addition to those whose yields are 8,000 lb. of milk or over, cows will be eligible for entry in future issues of the Register if their average yield for two consecutive years is not less than 6,500 lb.

The following are the principal memoranda and forms used in connection with the live-stock operations of the Board, and copies of them can be obtained free of charge on application to the Secretary, Board of Agriculture and Fisheries, Whitehall Place, London, S.W. 1 :—

- L. 1.—Memorandum on the Live Stock Scheme.
- L. 2.—Regulations as to Bull Grants.
- L. 3.—Regulations as to Heavy Horse Grants.
- L. 4.—Memorandum and Regulations as to Milk Record Grants.
- L. 11.—Regulations as to Boar Grants.

AN EXPERIMENT IN WAR TIME BEEF PRODUCTION.

T. B. WOOD, C.B.E., M.A.,

Drapers' Professor of Agriculture, Cambridge University.

THE experiment, of which an account is given below, originated at a meeting between Dr. R. B. Greig, of the Scottish Board of Agriculture, Mr. J. R. Campbell, of the Irish Department of Agriculture, and the writer, at which the minimum amount of cake required for winter beef production was discussed. A study of the literature showed practically only one direct experiment on the subject, namely, an experiment carried out at the Norfolk Agricultural Station in 1908, when 10 steers on a ration of $1\frac{1}{2}$ cwt. roots, 10 lb. chaff, and 1 lb. cotton cake per head per day, were found to increase in live weight at the rate of $1\frac{1}{4}$ lb. per head per day for 20 weeks, during which period they produced 78 tons of dung which was found to produce an excellent crop of mangolds when applied to the land at the rate of 10 tons per acre.

In view of the prospective shortage of cake, it was considered highly desirable to obtain more general information on this subject, and arrangements were made for carrying out feeding trials on beef production with a low cake ration in England, Scotland and Ireland. Accordingly, a scheme was prepared and trials were carried out at two stations in Norfolk, two stations in Scotland and three stations in Ireland.

The idea of the experiment was to feed a number of $2\frac{1}{2}$ -year-old steers on as many roots and as much straw as they would eat, supplemented with only $1\frac{1}{2}$ lb. per head per day of undecorticated cotton cake. It was also considered desirable that, where possible, the weights of litter consumed and of dung produced should be recorded, and that the animals should be slaughtered under such conditions that their carcass weights could be determined.

Outside these points, full discretion was left to the experimenters to adopt the ordinary practice of their district. Accordingly, the methods of feeding do not agree in every detail, but the results may be taken to show the extent to which $2\frac{1}{2}$ -year-old steers will increase in live weight on a cake ration of $1\frac{1}{2}$ lb. when fed otherwise according to local English, Scotch and Irish practice.

Looked at in this way, it is allowable to collect all the results into one table and to attempt to draw lessons from them as a whole, in spite of the variations in detail of the feeding and management.

Before this can be done, however, it may be advisable to state briefly how the trial was carried out at each centre.

Norfolk Agricultural Station, Little Snoring.—The 20 Irish steers, about $2\frac{1}{2}$ years old, bought in Ireland by Mr. Josias Cunningham of Belfast, were weighed the day after arrival and at once put upon the prescribed ration of roots, straw, hay and cake. The roots consumed were swedes for the first 12 weeks, for the thirteenth week swedes and mangolds mixed, and thereafter mangolds only. Cut oat straw was given and some good long hay. Barley straw was used for litter, and no doubt the animals picked out what they liked of it. The animals were housed in closed boxes.

All the animals were weighed and sold on the same day at the local market (Fakenham), the weights given being taken from the sale tickets. On account of scarcity of labour it was impossible to weigh either the litter or the dung, but from former trials it is probable that the litter amounted to nearly 30 lb. of straw per head per day, or a total of 35 tons, and the dung produced to rather more than 1 cwt. per head per day, or a total of 140 tons.

Half the animals were graded super, and half first grade. Six animals were followed to the slaughter-house in London, where they were found to yield from 54 to 57 per cent. of dressed carcass, averaging 55 per cent.

Field Dalling.—There was no weighbridge at this centre, and the weights given are taken from the weighbridge tickets at the port of shipment in Ireland and the sale tickets at the local market (Holt). Of the 20 animals, 13 were placed in the super grade, and 7 in the first grade. The animals, Irish $2\frac{1}{2}$ -year-old steers, were put on the prescribed rations immediately on arrival—roots, oat straw chaff and cake. For the first 9 weeks the roots were swedes, then followed one week of mixed swedes and mangolds, after which mangolds only were given. The animals were housed in a covered yard, and sold as they were judged to be ready, the average duration of feeding being 18 weeks. It was impossible to weigh either litter or dung, but the estimated amounts are :—

Litter, barley straw	32 $\frac{1}{2}$ tons.
Dung	126 „

Spencerfield.—The animals were Irish steers, similar to those used at the other stations, but they were kept nearly a month, partly on pasture and partly on roots and straw before being put on the experimental ration. The weights given are taken from weighings at the station at the beginning and end of the experimental period. This, no doubt, tends to scientific accuracy, but the method used at the Norfolk stations gives a better measure of the economic result. The roots used throughout the experimental period were swedes. Long oat straw was given, and the standard ration of $1\frac{1}{2}$ lb. of cake. The litter used and the dung produced were weighed, with the following result :—

Litter used	4 tons 1 cwt.
Dung produced	39 „ 3 „

The animals were sent by rail to Edinburgh at the end of the experimental period and lost in transit 58 lb. per head, or $4\frac{1}{2}$ per cent. of their live weight. The experiment was conducted by Mr. W. Bruce, B.Sc., of the Edinburgh and East of Scotland Agricultural College.

The experiments were under the direction of Professor Hendrick.

Cralbetone.—Two trials were made here, one with Irish steers similar to those used elsewhere, and a second with home-bred steers. The weights given are taken from weighings made at the farm on the first and last days of the experiment. As at Spencertfield, the animals were kept for about 3 weeks after arrival on a ration of turnips and straw before the trial commenced.

The roots used were yellow turnips for the first 6 weeks of the trial and swedes for the rest of the period. Oat straw was used for feeding. The amount of litter was 7 tons 6 cwt. of straw, and the weight of dung produced was 52 tons.

The cattle were marketed as they were considered ready, the average duration of feeding being 14 weeks in the case of the Irish steers and 18 weeks in the case of the home-breds. The average loss in live weight between the last weighing on the farm and the weighings made immediately before slaughter, after travelling, was $5\frac{1}{2}$ per cent.

Ballyhaise.—The cattle were Irish steers. Swedes were used throughout the trial, but the supply gave out at the end of 12 weeks, when the trial had to be stopped and the animals slaughtered. Hay was used in place of straw. The animals were tied up in stalls and the dung removed daily and heaped up. This greatly reduced both the

litter used and the dung produced, because the urine from the cattle was not absorbed by the litter, but allowed to drain into a liquid-manure tank. The actual amount of litter supplied was 7 lb. per head per day, or a total of 2 tons 2 cwt. The dung produced was 40 lb. per head per day, or a total of 12 tons, exclusive, of course, of the liquid manure. The weighings given are those taken at the beginning and end of the trial.

Athenry.—Irish steers were used. The roots were swedes at first, and later mangolds. Oat straw was fed and no hay. The cattle were housed in covered sheds. The amount of litter used was 28 lb. per head per day, or a total of 11 tons 4 cwt. The dung produced was 134 lb. per head per day, or a total of 53 tons 12 cwt. The animals were sold for slaughter as they were considered to be fit, the average duration of feeding being 15 weeks.

Glasnevin.—The cattle used were Irish steers. The ration included mangolds, oat straw, and a little hay and the standard allowance of cake. The animals were housed in covered sheds. The litter supplied was 13 lb. per head per day, or a total of 7 tons 14 cwt. of straw. The dung produced was 82 lb. per head per day, or a total of 48 tons 14 cwt. The weighings given are those made at the beginning and end of the trial. The animals were weighed again immediately before slaughter, and showed a loss in transit of nearly 8 per cent.

Results.—Particulars of numbers of cattle employed, duration of feeding, rations, increase in live weight, yield of carcass, litter supplied and manure produced, are given in Table I.

Although the feeding and treatment were not identical in every case, so that the results cannot be strictly averaged, they show quite clearly that stores about 2½ years old, provided they get an abundance of roots and good straw or hay will on as low a cake ration as 1½ lb. per head per day of undecorticated cotton cake, increase in weight at the rate of about 10 lb. per head per week, and in 15 to 20 weeks will produce a yield of about 56 per cent. of dressed carcass, which entitles them to be placed in the first grade. At the same time, they will produce if kept in covered yards about 7 tons of dung per head during the feeding period.

Five of the results are extraordinarily uniform, the increase in live weight being at the rate of 8 to 10 lb. per head per week. In two cases, namely at the Norfolk Agricultural Station and at Athenry this rate was greatly exceeded, possibly in the first case because the animals got a fair ration of good long hay. At Glasnevin, the rate of increase was considerably smaller, possibly on account of the small ration of roots. On the whole, the trials show that with a liberal allowance of roots and either good oat straw or hay, supplemented by a ration of 1½ lb. of cake per head per day, an average increase in live weight of about 1¼ lb. per head per day may be relied upon in

the case of good quality steers $2\frac{1}{2}$ years old or over. Whether younger animals would give similar results remains still in doubt.

It is important to compare these results with those obtained with pre-war feeding, when much larger cake rations were commonly used.

In the experiments carried out last winter, 95 store cattle weighing 910 cwt. 2 qr. 2 lb. produced fat cattle weighing 1,080 cwt. 2 qr. 19 lb., or a store beast weighing on the average 9 cwt. 2 qr. 9 lb. produced a fat beast weighing 11 cwt. 1 qr. 14 lb. The average yield of dressed carcass was 56 per cent., so that 11 cwt. 1 qr. 14 lb. yielded 6 cwt. 1 qr. 14 lb. of dressed meat.

In a series of experiments carried out in Norfolk during the years 1896 to 1899, 56 store cattle weighing 507 cwt. 10 lb. yielded fat cattle weighing 622 cwt. 1 qr. 6 lb. The average yield of dressed carcass was 59.5 per cent. From these figures a store beast weighing 9 cwt. 6 lb. produced a fat beast weighing 11 cwt. 13 lb., yielding 6 cwt. 2 qr. 14 lb. of dressed meat.

In last season's experiments, the average duration of feeding was 17 weeks and the cake ration $1\frac{1}{2}$ lb. per head per day. In the earlier experiments the average duration of feeding was 19 weeks and the average cake ration 8 lb. per head per day. The total cake consumed per head in the two cases was, therefore, $178\frac{1}{2}$ lb. and 1,064 lb. respectively.

For comparative purposes, the above figures have been recalculated on the basis of a store beast weighing 1,000 lb. :—

		<i>Total Cake Consumed.</i>	<i>Weight of Store.</i>	<i>Weight of Fat Beast.</i>	<i>Weight of Meat.</i>
1918		$178\frac{1}{2}$ lb.	1,000 lb.	1,187 lb.	665 lb.
1896-9		1,064 ..	1,000 ..	1,228 ..	731 ..

On last year's low cake ration, $178\frac{1}{2}$ lb. of cake resulted in the production of 655 lb. of meat. On the pre-war Norfolk cake ration of 8 lb. per head per day, 1,064 lb. of cake produced a further 66 lb. meat.

In these days of difficult importation, there can be no question that the low cake ration should be generally adopted. According to the above figures, the decrease in cake consumption from 8 lb. per head per day to $1\frac{1}{2}$ lb. per head per day only reduced the live weight produced by 3.3 per cent. and the meat by 9 per cent.

From the point of view of profit, the high cake ration was also a mistake. For each extra pound of beef produced 13 lb. of cake, costing about 2s., was consumed.

At the Scotch stations duplicate lots of cattle were fed on roots and straw without cake for comparison with the lots getting $1\frac{1}{2}$ lb. of cake in addition.

TABLE I.

Name of Station.	No. of Cattle.	Length of Feeding Weeks.	Ration per Head per Day.				Average Live Weight		Average Gain.	Av. Gain. per Week.	Yield of Carcass per cent. of Live Weight.	Litter Supplied per Head.	Manure Made per Head.

* Estimated from former experiments.

† Animals kept in tie-up stalls.

It is impossible to compare the results obtained with roots and straw with the above figures, for the roots and straw results refer only to about half the cattle. Comparing the cake and no cake lots, which were fed side by side, the use of $1\frac{1}{2}$ lb. of cake per head per day resulted in an increased production of meat of about 5 per cent. ; but no great reliance can be placed on this figure as it is based on the results of only a small number of animals.

It is certain that with an allowance of $1\frac{1}{2}$ to 2 cwt. of cake per head of cattle to be fattened next winter, beef can be satisfactorily produced. The yield of meat will probably be within 10 per cent. of the yield which would be obtained if a normal ration of cake were available.

If no cake at all can be allowed for beef production, the Scotch results suggest that beef can still be produced from roots and straw, but the yield of meat is likely to be reduced by a further 5 per cent. or by a total of 15 per cent. below the yield if a normal ration were available.

Economic Results.—The results may also be considered from the economic standpoint, for which purpose complete figures are available for the two Norfolk experiments. These figures include the cost of the cattle, the cost of the cake, and the amount realised by the sale of the cattle. Fortunately, too, the writer is in possession of complete figures for the cost of production of the home-grown foods on one of the farms. These are given below :—

Cost of Production of Home-grown Foods.

<i>Mangolds</i> : 10 acres grown in 1916.						£	s.	d.
Rent and rates	14	3	9
Labour	21	9	8
Horse labour	21	13	0
Manures and seed	54	3	10
Small items	1	0	5
General expenses ; including share of management, depreciation of implements, etc...						7	18	4
						<hr/>		
						£120	6	0
Less share of manurial residue and tillage carried forward to next crop					
						4	16	10
						<hr/>		
Cost of growing 10 acres						£115	9	2
						<hr/>		
Cost per acre						£11	11	0
						<hr/> <hr/>		

Assuming that the crop was 16 tons per acre, the average crop in Norfolk according to the Board of Agriculture returns, the cost per ton works out at 14s. 9d., or, say, 15s.

Swedes : 26½ acres grown in 1916.						£	s.	d.
Rent and rates	37	12	0
Labour	42	4	0
Horse labour	55	3	10
Manures and seed	30	3	9
Small items	2	10	10
General expenses : including share of management, depreciation of implements, etc...						12	5	1
						<u>£179 19 6</u>		
Less share of manurial residue and tillage carried forward to next crop						15	3	5
Cost of growing 26½ acres						<u>£164 16 1</u>		
Cost per acre						<u>£6 5 0</u>		

Assuming that the crop was 12 tons per acre, the average crop in Norfolk according to the Board of Agriculture returns, the cost per ton works out at 10s. 6d.

Seeds Hay : 24½ acres grown in 1916.						£	s.	d.
Rent and rates	33	15	3
Labour	12	5	7
Horse labour	10	4	3
Seed	12	12	0
Share of tillage, etc., of preceding crop brought forward						35	7	6
Small items	2	10	10
General expenses : including share of management, insurance, depreciation of implements, etc.						7	10	11
						<u>£115 4 4</u>		
Less share of manurial residue etc., carried forward to next crop						17	13	9
Cost of growing 24½ acres						<u>£97 10 7</u>		
Less aftermath charged to sheep						26	1	0
Cost of 24½ acres of hay						<u>£71 9 7</u>		
Cost per acre						<u>£2 18 0</u>		

Assuming that the yield of hay was 25 cwt. per acre, the average according to the Board of Agriculture returns, the cost per ton works out at £2 6s. 5d.

Oat Straw :—22 acres grown in 1916.						£	s.	d.
Rent and rates	33	0	0
Labour	35	8	9
Horse labour	15	5	0
Seed	11	0	0
Thrashing	10	18	2
General expenses : including share of management, insurance, depreciation of implements, and manures						19	0	6
Total						<u>£124 12 5</u>		

To determine the separate cost of the straw the following method was adopted: The 22 acres produced 168 qr. of grain and 22 tons of straw. The average market prices for oats and oat straw in 1916 were for oats 40s. per qr., and for oat straw 30s. per ton. The market value of the total produce was, therefore—

					£
168 qr. oats at 40s.	336
22 tons straw at 30s.	33
					<hr/>
Total	£369
					<hr/>

The market value of the straw was, therefore, almost exactly one-eleventh of the market value of the total produce. Assuming that the cost of production is also shared between grain and straw in this proportion, the cost of production of 22 tons of straw is one-eleventh of £124 12s. 5d., or £11 3s. 10d. (*i.e.*, 10s. per ton).

Barley straw works out at exactly the same figure.

It appears, therefore, that the cost of production of home-grown foods at one of the Norfolk stations in 1916 was as follows :—

						<i>Cost of Production</i>		
						<i>per Ton.</i>		
						£	s.	d.
Mangolds	0	15	0
Swedes	0	10	6
Seeds hay	2	6	5
Oat and barley straw	0	10	0

Unfortunately, the actual costs of production for 1917 are not available, but it is certain that between these two seasons labour, seed manures, and in fact all items except rent, had risen, and must have increased the cost of production. On the assumption that all items, except rent, had risen between 1916 and 1917 by 33 per cent., then the cost of production in 1917 becomes—

						<i>Cost of Production</i>		
						<i>per Ton.</i>		
						£	s.	d.
Mangolds	0	18	6
Swedes	0	13	0
Seeds hay	2	14	0
Oat and barley straw	0	13	0

These figures cannot pretend to possess any general accuracy, since the greatest factor in determining them is the yield per acre. It costs as much to produce a bad crop as a good one.

In these circumstances, it seems advisable to round off the figures as follows :—

Estimated Costs of Production per Ton, 1917.

	£	s.	d.
Mangolds	1	0	0
Swedes	0	15	0
Seeds hay.. .. .	2	15	0
Oat and barley straw .. .	0	15	0
Oat straw chaff	1	0	0

Adopting these figures, the financial results of the two Norfolk experiments work out as follows :—

Norfolk Agricultural Station, 1917.

	£	s.	d.		£	s.	d.
To cost of 20 bullocks, 186 cwt. 2 st. (68s. 4d. per cwt. on the farm) ..	636	17	6	By sale of 20 bullocks, 246 cwt. 7 st. (75s. 6d. per cwt.) ..	932	3	7
Cost of 131 tons 13 cwt. swedes at 15s. per ton..	98	15	0	Value of 140 tons dung at 10s. per ton	70	0	0
Cost of 95 tons 10½ cwt. mangolds at 20s. per ton	95	10	0				
Cost of 3 tons 16½ cwt. oat straw chaff at 20s. per ton	3	17	0				
Cost of 6 tons 3½ cwt. long hay at 55s. per ton	17	0	0				
Cost of 1 ton 17½ cwt. cotton cake at £16/12/6 per ton	31	5	0				
Cost of 35 tons barley straw for litter at 15s. per ton	26	5	0				
Cost of labour at 1s. 6d. per head per week ..	30	0	0				
Profit on feeding ..	62	14	1				
	<u>£1,002</u>	<u>3</u>	<u>7</u>		<u>£1,002</u>	<u>3</u>	<u>7</u>

The above figures show that if the dung is valued at 10s. per ton, the 20 weeks' feeding of 20 cattle resulted in a profit to the farm of £62 14s. 1d. To this result two factors chiefly contributed. In the first place, the cattle were bought at 7s. per cwt. below the selling price. Secondly, the rate of increase, 17 lb. per head per week, was exceptionally high.

Field Dalling.

	£	s.	d.		£	s.	d.
To cost of 20 bullocks, 200 cwt. (72s. 2d. per cwt. on the farm)	721	11	2	By sale of 20 bullocks, 233 cwt. 3 st. (75s. 9½d. per cwt.)	884	11	3
Cost of 112 tons swedes at 15s. per ton ..	84	0	0	Value of 126 tons dung at 10s. per ton	63	0	0
Cost of 90 tons mangolds at 20s. per ton ..	90	0	0	Loss on feeding ..	34	8	6
Cost of 6 tons oat straw chaff at 20s. per ton ..	6	0	0				
Cost of 1¼ tons cotton cake at £16 12s. 6d. per ton	20	1	10				
Cost of 32½ tons barley straw for litter at 15s. per ton	24	6	0				
Cost of labour : 18 weeks at 1s. 6d. per head per week	27	0	0				
	£981	19	9		£981	19	9

The Field Dalling trial was evidently not so satisfactory from a financial point of view. No profit was made, and if the whole expenses are charged to the dung it cost £97 8s. 6d. for an estimated quantity of 126 tons, which works out at 15s. 6d. per ton. This seems a high cost for dung, but the writer, who has kept accounts for many years on the lines shown above, has known dung to cost as much even before the War. It will be noticed that the bullocks fed at Field Dalling cost as stores 72s. 2d. per cwt., or 3s. 10d. per cwt. more than the bullocks fed at Little Snoring. This difference in price amounts to £38 6s. 8d. on the 20 bullocks. If the Field Dalling stores had been bought at the lower price, the cost of the dung per ton would have been reduced to less than 10s. per ton, which is not an unreasonable price with wheat at its present level. This serves to show the predominant importance of the price of the stores in determining the cost of production of beef. The following table illustrates this point in the case of the Norfolk stations :—

Items in Cost of Production of Beef.

	Little Snoring.	Field Dalling.	Average.
Cost of stores ..	67·7	73·5	70·6
Cost of food :—			
Roots	20·7	17·7	
Straw	·4	·6	
Hay	1·8	—	
Cake	3·3	2·9	
	26·2	21·2	23·7
Cost of litter ..	2·9	2·5	2·7
Cost of labour ..	3·2	2·8	3·0
	100·0	100·0	100·0

This table shows that the cost of the stores amounted to about 70 per cent. of the cost of the finished animal and was, therefore, by far the largest item in the cost of beef production. The most important point, therefore, in producing beef is to be able to buy stores at a reasonable price. The Little Snoring cattle were bought at 7s. per cwt. below the selling price, the daily increase was exceptional, and a profit was made. The Field Dalling stores cost only 3s. 6d. per cwt. less than the selling price. they made a more usual rate of increase, and, in consequence, the dung they made worked out at a very high price. If stores can be bought somewhere between these two prices, say, at 5s. per live cwt. below selling price for beef, economic feeding should result in the production of dung at a reasonable price.

The food is the next most important item, costing even on the low cake ration used nearly 24 per cent. of the whole cost of production.

Labour and litter are both small items, amounting to about 3 per cent. each.

It is, of course, desirable to economise in food and in labour, but by far the most important point is to economise in buying the stores, which should cost at least 5s. per live cwt. less than the price at which the finished animals will be sold.

THE NEED FOR CAUTION IN THE FEEDING OF LIVE STOCK UNDER PRESENT CONDITIONS.

DIFFICULTIES of food-supply are to-day common to both man and beast. In the past, days of abundant supplies certain foods, such as the cereal and pulse grains, served equally for both, but in the present conditions of relative scarcity the needs of human nutrition leave little margin of such foods for the use of live stock. Moreover, certain other feeding-stuffs which were formerly imported in large quantities are now available only in greatly diminished amount, with the result that the total supplies of concentrated feeding-stuffs available for live stock are probably barely half those available in the days of peace.

There is no need to enlarge upon the difficulties which this shortage has occasioned to owners of live stock, but it is desirable to emphasise the increased obligation placed upon them for the exercise of the greatest care in the modification

of rations, and particularly in the hardly avoidable introduction of little tried, or possibly untried, new feeding-stuffs.

Materials are now finding use as feeding-stuffs which before the War were entirely unknown as such to the farmer, although many of them served as ingredients of proprietary compound cakes and meals. Some of these less familiar materials, though not in common use here before, are well proven and known to be generally satisfactory, but, as the deficit of food supplies has increased, there has been a growing tendency to add to the list materials of very doubtful feeding value, if not indeed actually injurious to stock.

In view of the increasing difficulties with which manufacturers of feeding-stuffs have been confronted during the War, it is hardly to be wondered at that the average quality of animal feeding-stuffs is now considerably below that of pre-war days. Cases are frequently reported of materials being sold as feeding-stuffs which on examination prove to be, if not entirely worthless, at least extremely poor value for the price charged. As an example may be cited the case of a "horse mixture," certified by Professor Wooldridge, of the Royal Veterinary College, to be essentially "oat and barley husks, chopped straw, and meagre traces of hay; complete absence of corn or grain of any kind."

Apart from this increase in the sale of low-grade materials there are signs of increase in losses of stock by poisoning due to the use of materials either entirely unsafe to feed or usable only in relatively small quantity. This has unfortunately been the case, for example, in the use of rape cake, especially when contaminated by mustard seed. The risk of poisoning by the use of such cake was well recognised many years ago, and led to the disuse of rape cake for feeding, except as an ingredient of compound cakes. Trouble has also been experienced recently in the use of sesame cake, in which the poisonous ingredient is oxalic acid. In both cases the experience of different farmers supplied from the same consignment of cake has varied greatly, many having observed no ill effects on their stock. This suggests that in the cases where trouble has arisen the rape or sesame cake may have been fed in unduly large quantities or otherwise so injudiciously dealt with as to afford special opportunities for the development of the injurious principles lying dormant in these materials.

A few cases of trouble do not warrant a wholesale condemnation of these feeding-materials, since the consignments which

have caused trouble represent only a small fraction of the total consumption, and in the great majority of cases no such trouble has been experienced.

The same cannot be said, however, with regard to the feeding of castor-oil beans to stock, which has recently been the cause of many cases of poisoning of horses. It cannot be too strongly emphasised that castor-oil beans are entirely different from ordinary beans and must on no account be fed to stock of any description. This does not necessarily apply to the castor meal from which the oil has been removed at a high temperature. This is said to be safe to use, but the prudent man will proceed cautiously in feeding it until satisfied that it is harmless.

The foregoing examples illustrate clearly the need for increased care on the part of the stock-owner if losses of stock are to be prevented. Various suggestions for attaining greater security in this direction were recently put forward in a letter to *The Times*, by Professor G. D. Lander, D.Sc., of the Royal Veterinary College, and are embodied in the following paragraphs :—

1. In purchasing feeding-stuffs all possible information as to the real nature of the material should be obtained before the order is placed. It is not sufficient to have a guarantee of the contents of albuminoids, oil, etc., since such figures give no assurance that deleterious ingredients are not present.
2. The user should avail himself to the full of the services of the district agricultural analyst and of the expert advice obtainable gratis from the County Organiser or Agricultural College in his area. All material of unusual appearance, especially foreign grains or seeds, should be submitted to qualified experts for identification before being used.
3. In general, low-priced material should be avoided unless there is clear evidence that it is good value. Most of the trouble reported in the use of purchased feeding-stuffs arises from the use of low-priced material. Such material is generally either low-grade material or damaged high-grade material, and in either case can rarely give satisfaction to the user.
4. It is useless to try to make up for bad food by dosing with "alterative" or "condition powders," many of them dangerous. No amount of medicine will

make good the lack of nutritious elements in the food. The safest, and probably most economical plan, is to discard such food entirely.

5. Changes of diet should be made gradually, especially where they involve the introduction of new foods. Animals are generally suspicious of new foods and often reject for a while material which they subsequently eat readily. This is a very common experience with palm kernel cake, and the impatient farmer who rejects it on a few days' unfavourable experience will deny himself one of the most useful and most abundant feeding-stuffs at present available.
6. In the case of an entirely new food of unknown feeding characteristics, it is only common prudence to try it first on a single isolated animal, and that the least valuable.
7. The risk of trouble is considerably reduced by using a mixture of concentrated foods, instead of restricting the animal to a single one. There are other sound reasons for making this a general practice, and it should be the invariable rule in using foodstuffs that have not been widely used and found quite safe. In the case of cattle, cows or horses, caution is generally needed—certainly in the case of new foods—in increasing the amount of any one feeding-stuff beyond 2 or 3 lb. per day. For sheep and pigs the corresponding limit is roughly $\frac{1}{2}$ lb.

The farmer should remember that in using a new or hitherto untried food he is really carrying out an experiment and must proceed therefore by gradual stages, watching the effects at each stage before passing on to the next. So long as supplies of feeding-stuffs remain short, and the farmer is often compelled to take what is offered rather than what he would like, so long must risks be taken which would be avoided in normal times, and the only safe way to reduce these risks is to exercise correspondingly greater care in purchase and to have recourse to experimental methods in use.

(NOTE.—*This article is also issued as Food Production Leaflet No. 49. Copies may be obtained post free on application.*)

RABBIT KEEPING.

THE objects of this article are to give reasons why rabbits should be kept by everyone who has the necessary and very simple means of rearing them, and to show how the keeping of rabbits may be economically and successfully carried on by amateurs who have had no previous experience in rearing them.

The chief reasons why it is important that the stock of rabbits in the country should be largely increased is that if this is done a large supply of meat will be available to supplement the present short rations.

As indicating the amount of food which may be produced by rearing rabbits for the table, it may be mentioned that the total weight of the progeny produced in the two breeding seasons by a healthy doe mated with a healthy buck is not less than 1 cwt. Furthermore, it should be borne in mind that rabbit flesh at the present time is a particularly valuable food, because of its richness in nitrogenous or flesh-forming food substances.

The only drawback to rabbit flesh as an article of food lies in the relatively small quantity of fat which it contains. For this reason the best course that can be followed by all who are able to adopt it is to combine rabbit-keeping with pig-keeping, for the fat supplied by the one animal supplements the nitrogenous food supplied by the other. Rabbit flesh and bacon together will supply a meal as rich in food as is beef or mutton. For example, 3 lb. of rabbit and 1 lb. of bacon would provide more nitrogenous and fatty food than is provided by 4 lb. of beef.

One of the greatest advantages of rabbit-keeping is its small cost. Of all the food-producing domestic animals the rabbit is the one which thrives on the simplest food, and indeed during seven months of the year its food should cost nothing beyond the trouble of collecting it. In winter the cost of food of an adult rabbit, even where all of it has to be bought, should not exceed 3*d.* per week.

The accommodation which rabbits require is of the simplest, and a sugar box in a back yard will make a thoroughly satisfactory hutch, provided that it is weather- and draught-proof, and well ventilated.

No one need be deterred from keeping rabbits by lack of expert knowledge, and by following the advice here given any amateur should be able to rear rabbits for the table. An amateur should begin with young rabbits, for to breed rabbits

profitably requires great care, and should not be undertaken until experience in keeping rabbits has been gained.

BREEDS OF TABLE RABBITS.—The breeds which are to be classed as table rabbits are :—Flemish Giant, Belgian Hare, Silvers, English, Blue Beveren, Black and Tan, Himalayan, Imperial, Japanese, Havana, Polish, and Dutch.

Angoras, which are also classed among the utility breeds, are chiefly reared for their valuable fur and “ wool ” which form in France the raw material of an important home industry.

There is no “ best breed ” of table rabbit.

The best table rabbit is that which produces the greatest amount of meat in the shortest time at the lowest cost, and therefore the “ points ” of a first-class table rabbit are :—

1. Hardiness of constitution.
2. Prolificness. (This does not mean so much the production of large litters as the ability to rear a large number of strong and healthy young).
3. Early maturity (quick growers).
4. Economic feeding (quick growers and small eaters).
5. Compact body.
6. Small bones.
7. Minimum of offal in “ dressing ” for the market.

Expert rabbit-keepers seek to secure these points by crossing suitable breeds. Some breeders believe in a cross between two of the large breeds as the ideal table rabbit. Others reject this cross on the ground that the offal at the killing age (bones, intestine and skin) is high, and prefer medium breeds because they are small eaters, mature early, and are close bodied, firm fleshed and small boned, with the minimum of offal. They point out, for instance, that while the Dutch is a small rabbit, the percentage of offal in its carcass is lower and that of meat is higher than in the large breeds.

As favourite crosses may be mentioned :—

Belgian Hare Doe	by Flemish Giant Buck.
Flemish Giant, Silver Doe, or any }	
Doe of the medium breeds .. }	.. Belgian Hare Buck.
Flemish, Belgian or English Doe Silver Buck.
Flemish, Belgian Hare, or Silver }	
Cross Blue Beveren.

Under existing circumstances, however, it is no longer a question of favourite crosses, but of getting any breeding stock at all. Those who intend to take up the breeding of rabbits or increase their breeding stock should obtain does of any of the breeds mentioned, including any from the above crosses, provided the does are healthy and of hardy constitution. The doe should be mated with a Pure-bred Flemish Giant, Belgian Hare or Silver Buck. The service of such bucks can be obtained

at the nearest Stud Rabbit Centre. *A list of these centres can be obtained on application to the Secretary of the County Horticultural Sub-Committee* or to the Food Production Department, 72, Victoria Street, London, S.W. 1.*

BREEDING.—*Breeding Stock.*—The buck should be strong, with hard and firm flesh, and a fine, vigorous appearance. The doe should be lean and firm fleshed, with a coat in perfect condition.

Breeding Age.—Bucks (of all breeds) reach breeding ages at about nine months. Does—Dutch, Polish, and Himalayans—at six months; Flemish Giants, eight months; all other breeds, seven months.

Mating.—For mating use a young buck with an older doe, or a young doe with an older buck.

“Season.”—A doe indicates her readiness to be mated by general restlessness, stamping the floor with her hind feet, trying to burrow in the corner of the hutch, plucking fur from her chest, and carrying about bits of hay.

As soon as these signs are noted the doe should be placed in the buck's hutch, and should be left there for a short time. It would be well for beginners to consult an experienced rabbit breeder on these points, as they are most important.

Three weeks after mating the doe begins to make her nest in the darkest corner of the hutch. Many breeders supply her at this period with a separate nest box; but this is not necessary. A better plan is to shut off the darker part of the hutch (where the door is) by a movable partition. The doe will choose the darkest corner of this part, make her nest of hay and line it with her fur. She should now have an ample supply of sweet hay, green stuff (or roots) and water.

Gestation.—The young rabbits are born thirty days after mating. During the whole period of gestation and while she is nursing her litter, the doe should be kept perfectly quiet and protected from being worried by mice or rats, or frightened by cats or dogs. Towards the end of this period the hutch should be thoroughly cleaned, but without disturbance to the nest.

Three days after the young are born, the hutch should be examined and any dead young which the doe may have carried to a corner of the hutch should be removed.

If it is necessary to handle the litter, the rabbit-keeper should first rub his hands with sawdust from the hutch. Breeding does object to the “human” scent, and will some-

* Addressed c/o The Secretary, The Agricultural Executive Committee.

times abandon a litter for that reason. If the doe is on the litter she may be coaxed away from it with a tasty morsel of food.

Weaning.—The young may be taken from the doe and placed in another hutch in summer, when they are four weeks old, or five weeks in winter.

Winter Breeding.—Where warm hutches and the necessary food are available, breeding may be carried on right through the winter. It is, however, not advisable to mate maiden does after October. During the winter the breeding hutches should have an ample supply of sawdust and straw for litter, and the doe will also require more liberal feeding.

HOUSING.—Any shed, stable or outhouse is suitable for housing rabbits so long as it is dry, light, free from draughts, and well ventilated. Cellars are not suitable.

To economise space, and to give better control, rabbits should be kept in hutches.

A simple but serviceable hutch is illustrated in Fig. 1.

FIG. 1.—A Simple Hutch.

For breeding-does or bucks of the smaller breeds, such as the Dutch Tans and Silvers, the size of the hutch need not exceed 2 ft. 6 in. by 1 ft. 8 in., but a larger hutch should be provided if material and space are available.

The open front is made of strips of wood nailed on 1 in. apart. The door moves on hinges made of leather or strong canvas. For fastening use a staple, a strip of strong leather with a slit and a piece of wood fastened with string to the door.

For the larger breeds the dimensions of the breeding hutch should be 4 ft. 6 in. by 2 ft. by 2 ft.

A hutch of this size is also suitable for the rearing of young rabbits for the table, and will comfortably house six.

A stack hutch (Fig. 2) is recommended where rabbits are to be kept out of doors. It should be made of strong seasoned material and covered with roofing felt. Provision should be made for fixing a canvas screen over the wire netting during unfavourable weather. The stack hutch should be placed in a sheltered position, preferably with a southern aspect. The roof should project about 18 in. beyond the hutches, and space

FIG. 2.—A Stack Hutch.

should be provided between the roof of the top hutch and the roof of the stack for storing food and tools.

The floor and 6 in. of the sides of every hutch should be well tarred and sanded to prevent urine from soaking into the wood. The hutches should be thoroughly whitewashed twice a year. The breeding hutch should be lime-washed directly the young are weaned, and the fattening hutches when the rabbits are removed.

Open-air hutches are used for keeping rabbits on grass (e.g., lawns). A hutch of this kind is known as the Morant hutch, and consists of a box and a wire netting extension. The box has a door, as shown in Fig. 3, and an opening cut in the side adjoining the wire run to allow the rabbit to pass in and out.

The wire netting cage may have a boarded end, and the netting should be as follows: bottom, $1\frac{1}{2}$ -in. mesh; roof and front, $\frac{3}{4}$ -in. mesh.

The front should be 2 ft. high and the back 1 ft. 8 in. high, to produce a sloping roof.

A hutch of this kind accommodates one adult rabbit. It should be moved to a fresh patch every morning and evening, except in wet weather. In the south this system can be adopted successfully from March to October; in the north usually from May to September.

FIG. 3.—Morant Hutch, for keeping rabbits out of doors.

Bedding.—For litter peat moss, dry earth, sifted ashes, straw or sawdust may be used. Peat moss is not a cheap litter, but makes with the rabbit droppings a valuable manure. Sawdust on the other hand is cheap and very useful as litter, but the hutch cleanings cannot be used as manure until they have thoroughly rotted.

Cleaning.—Hutches should be thoroughly cleaned twice a week and be well littered. The corner, which is as a rule used regularly by the rabbits, should be cleaned every day and be well littered.

Utensils Required.—A short-handled hoe, shovel, hand-brush and two buckets (one for the clean litter and one for the hutch cleanings) are required.

Equipment for the Hutch.—Feeding-trough, drinking-vessel, hayrack. The best troughs are those of glazed earthenware, made with a flange which prevents waste of food.

FOOD FOR RABBITS.—Expert rabbit-breeders, including the most prominent breeders of exhibition rabbits, are agreed that oats, wheat, and millers' offals do not constitute an indispensable part of the diet, either of breeding stock or of young rabbits which are being reared and finished for the table.

A rabbit, like any other animal, needs :—

1. Enough food, and of a sufficient variety, to maintain it in a state of health (maintenance ration), and
2. In addition, as much more food of the right kind as will make it thrive (production ration).

In the days before the War, when corn was cheap, hutch rabbits were often extravagantly fed, with the result that much of the food remained undigested and was wasted.

In the present conditions, when corn is dear and often unobtainable, it is neither desirable nor necessary that cereals of any kind should be used for feeding rabbits. It is therefore necessary to provide rations from other sources, and to use for this purpose foods which are plentiful and might otherwise be wasted.

To supply an efficiency ration it is desirable to use a mixture of foodstuffs in such proportion that the average composition of the food is similar to that of the food of the animals in their natural state. Fortunately, the experience of many successful rabbit-breeders is available for this purpose, for not a few of them, including exhibitors, had already, long before the War, abandoned the idea that the food of rabbits must contain a certain proportion of cereals (oats, wheat, barley, bran, middlings). They proved by the prizes which they took for exhibition rabbits that it is possible to exhibit successfully rabbits fed on green stuffs, roots, and hay, and bred from stock fed on a similar diet.

Summer Food.—*From the Garden and Allotment.*—Pea haulms, celery, chicory, grass (including lawn mowings), leaves of lettuce, cabbage, broccoli, cauliflowers, beet, sugar beet, nasturtium, pea pods, strawberry runners, sunflower leaves, tops of carrots, radishes, turnips, mustard, cress, rape, etc.

Wild Food.—Bindweed, comfrey, chickweed, clover (red and white), coltsfoot, dandelion, groundsel, marshmallow, plantain, shepherd's purse, sow thistle, wild chicory, yarrow, couch and young bracken rhizomes.

Farm Crops.—Clover (red and white), lucerne, maize, sainfoin, tares, vetches, hay, mangolds, turnips, swedes, etc.

Waste from the Kitchen.—Potato peelings (well crisped in the oven, or boiled with chats, and given as mash), apple peelings, waste green stuff.

Other Waste Foods.—Prunings from fruit trees and bushes (apple, pear, nut, blackberry); clippings from hawthorn hedges, elm, oak, lime, poplar, mulberry, willow, broom, furze.

Winter Food.—Beetroot, carrots, kohl rabi, mangolds, parsnips, potatoes (boiled or baked), swedes, turnips, split cabbage stalks, hay, acorns (three per head per day), sunflower seed (half a dozen per head per day during cold weather).

NOTES ON THE FEEDING OF RABBITS.—1. The whole art of rational feeding is to give rabbits as far as possible every day a large variety of food. This is easy enough in the summer, but should also be aimed at in the winter when the choice of food is more limited.

2. Generally speaking, a rabbit thrives on a daily supply of food equal to 2 oz. per pound of its live weight. For a 6-lb. rabbit this would mean :—

10 oz. of green food (or, in winter, roots).
2 „ hay (divided into two meals).

In practice, the rule is to study the appetite of each individual rabbit, and to give each one only as much food (green food, roots and mashes) as it will clear up at a meal. The eating of food, which has been left over from a meal and become stale or contaminated, is often the cause of digestive trouble in rabbits. They should, however, be kept well supplied with hay.

3. Rabbits should never be given stale or frosted food. During frost roots and other food should be kept all night near the kitchen stove so that they are well thawed.

4. Feeding should be at regular hours. Ordinarily it is a satisfactory plan to feed twice a day—in the morning and in the evening. It does not matter greatly which hours are chosen—6 a.m. and 6 p.m., or earlier or later—but once the hours have been fixed they should be kept.

Young rabbits which are being weaned should be fed three or even four times a day.

Breeding does should be fed three times a day, as follows :—

Morning.—Warm mash of boiled small potatoes and peelings mixed with clover hay chaff.

Noon.—Green food (or roots) and hay.

Night.—Green food (or roots) and hay.

5. The rabbits should be kept supplied with fresh water. The water should be changed regularly once a day, and during very hot weather twice a day.

6. Great care should be taken to change the diet in the autumn very gradually from greens to roots, and in the spring back again to greens.

7. Buying rabbit food in small quantities makes rabbit-keeping unnecessarily expensive ; breeders should club together and buy roots, hay, etc., in bulk.

8. When buying stock, rabbit keepers should ascertain the diet on which it has been fed. This knowledge will prevent all the trouble caused by a sudden, and it may be radical change from one dietary to another.

Fattening.—Before putting the young six-weeks-old rabbits into the fattening pen they should be looked over with the object of picking out any well-marked specimens for breeding purposes.

The fattening of the young rabbits begins on the day they are born. The whole art of keeping them growing is to feed the doe on a carefully selected variety of foods (see p. 570).

Where large numbers of rabbits are being reared for the table they should be kept in separate rearing pens according to sex, and also, so far as possible, according to age.

If they have been well bred, fed and treated, they will be ready for killing at 14 or 16 weeks, and yield a dressed carcass of about $3\frac{1}{2}$ lb., the favourite market weight. Larger weights (older rabbits) cost more to produce and fetch less money.

NOTE.—*The Compost Heap.*—Make a wall of turves, enclosing a small space of suitable size in a dry and sheltered part of the garden. Leave an opening in the side to give access to the enclosure.

Spread the solid matter removed from the hutch evenly over the surface of the ground and water the liquids over the layer of solid matter.

The heap takes a few months to make, and the contents should be turned at least once. Wherever possible the heap should be under cover, but where this is not practicable sprinkle dry, sifted earth occasionally over the heap. A valuable manure is thus obtained for the garden or allotment.

Preparing for the Table and the Market.—Full particulars on preparing rabbits for the table and market are given in a leaflet printed by the National Utility Rabbit Association. Copies may be obtained on application to the Food Production Department, 72, Victoria Street, London, S.W. 1.

(This article is also issued as Leaflet No. 265, a revise of which is about to be issued. Copies may be obtained on application.)

ACORNS AS FOOD FOR POULTRY.

HAROLD T. CRANFIELD,

Agricultural Chemist to the Midland Agricultural and Dairy College.

OWING to the increasing shortage of feeding stuffs it has been necessary, during the past few months, to place severe restrictions on the use of corn and meals for feeding poultry. In consequence poultry-keepers are experiencing great difficulty in obtaining sufficient supplies to keep their flocks, and there is not the slightest doubt that the situation will become very acute during the coming autumn and winter.

Poultry foods can, generally speaking, be divided into three classes, viz., corn, meals, and green stuff (vegetables, etc.), all of which are generally considered necessary for the successful rearing and keeping of poultry. Green stuff will not present any difficulty, and meals can still be obtained in limited quantities, although their feeding qualities are in many cases rather poor. Poultry-keepers, however, undoubtedly find supplies of corn exceedingly scarce.

Corn is practically a necessity for stock and laying birds, and it would be next to impossible to attempt to keep poultry for egg production without it. The grains used for poultry are wheat, rye, barley, oats, maize and various foreign seeds. Wheat, barley and rye are prohibited, foreign seeds are practically non-obtainable, and supplies of maize are very difficult to obtain. Consequently, oats constitute the only corn now available, and, since inferior (*i.e.* very husky) grain only can be utilised, this may prove a very inefficient corn ration.

Substitutes for corn have been suggested from many quarters. Sunflower seeds are recommended, but the sunflower requires land and cultivation, while the seeds are too rich in oil to prove a good substitute for corn.

The solution of the problem appears to the author to be found in the utilisation of some existing fruit or seed growing wild in this country, and hitherto of little or no economic importance. He considers that the most promising material is the acorn, and in this article are given the results of a brief investigation into the possibility of replacing the corn ration of poultry by this product of our forests and woods.

Although there have been experiments in the past with a view to utilising acorns as food for cattle (a review of which appeared in this *Journal*, No. 6, Vol. XXI., 1914-15), yet the only suggestion of which the author is aware, that this fruit

could be used as a poultry food, occurs in a paper by Petermann (*Die Landw. Versuchstionen*, LXXXII. 1, u. II., p. 93). This author briefly states that he considers acorns dried and ground into meal a good food for poultry.

It is well known that pigeons, pheasants and other wild birds eat acorns with avidity in the autumn, and with apparently no harmful results. Consequently, it does not appear that the feeding of acorns to poultry would be at all risky, and, since their feeding value is considerable, the collection and utilisation of this otherwise waste material would help in no small measure the efforts to maintain the poultry industry in this country.

The following experiment was therefore carried out :—

Acorns from several trees (at least two varieties) were collected last autumn. Owing to unfavourable weather the fruit was rather wet, and a small proportion had begun to sprout. The acorns were spread out in thin layers on sacks in a room, and allowed to remain until surface dry. They were then placed on trays in a cupboard warmed by a hot-water tank, and left there for several weeks. By this time the acorns had become thoroughly dry, the husks being quite brittle and the kernels as hard as maize. The acorns were then kibbled, and the fine meal was sifted out, the husks being completely loosened from the kernels during this operation.

An analysis of the kernels was made, the results being as follows :—

Moisture	13.86
Oil	4.57
Albuminoids	7.88
Soluble carbohydrates	67.82
Fibre	3.63
Ash	2.24
	<hr/>
	100.00

These figures agree very well with published analyses of dried acorn kernels. This foodstuff is quite comparable in composition with corn, the feeding value according to the analysis being similar to that of a mixture of oats and maize, the albuminoids only being somewhat less.

Seventeen birds in full lay were selected—twelve pullets and five two-year-old birds. Before commencing the acorn feeding the birds were receiving the following ration per bird per day :—

Soft Food—1 oz. Fish meal.

1 oz. Sharps.

Cooked vegetables.

Hard Food—1½ oz. wheat screenings, oats, and maize.

In the first week of the experiment the corn was reduced to 1 oz. per bird per day, and $\frac{1}{2}$ oz. of kibbled acorns was added (*i.e.*, $\frac{1}{2}$ oz. of the kernels, which constituted about 80 per cent. of the whole dried acorn).

In the second week the remainder of the corn was stopped and 1 oz. of kibbled acorns was substituted. At the beginning of the third week $\frac{1}{2}$ oz. of sharps in the soft food was replaced by $\frac{1}{2}$ oz. acorn meal (sifted out after kibbling), each bird thus receiving 2 oz. of acorn kernels per day.

It is interesting to note that the birds did not attempt to eat the husks.

The birds were watched very carefully for any adverse effects, but none appeared. They picked up the acorns very eagerly from the first, and throughout the experiment appeared to relish them. The acorns had a slightly binding effect, but this counteracted the rather laxative property of the fish meal, and thus rendered the excreta quite normal.

The egg record was as follows:—

—	Two Weeks previous to Experiment.		Acorn Feeding.			
	First.	Second.	$\frac{1}{2}$ oz. First Week.	1 $\frac{1}{2}$ oz. Second Week.	2 oz. Third Week.	2 oz. Fourth Week.
No. of eggs ..	77	78	73	71	73	72
No. of birds in lay	17	17	16*	15†	15†	15†
No. of eggs per bird per week	4.53	4.59	4.56	4.73	4.87	4.80

* One bird broody.

† One bird broody and one sitting.

It would appear from this record that the acorns had no adverse influence on the egg production, and, although one cannot draw too hasty conclusions from this brief experiment, yet it is quite certain that if this food had possessed unsuitable properties or a very low feeding value, the egg production would have suffered.

The experiment was discontinued at the end of the fourth week of acorn feeding, the supply of acorns being exhausted.

It is stated in *Fühlings Landwirtschaftliche Zeitung* (1904, p. 808) that acorns fed in too large quantities to hens caused a more or less black discoloration of the egg yolk. Eggs from the experiment recorded above were examined from time to time, but no discolouration was noticed—in fact the eggs were

not distinguishable from those laid before the acorn feeding commenced, both as regards colour and flavour.

It is perhaps a matter of difficulty to give a value to dried acorn kernels at the present time, since at the moment feeding value by no means controls prices. In the author's opinion dried acorn kernels should prove to be at least equal in feeding value to, and certainly much more digestible than, the low grade oats which have been obtainable in limited quantities for poultry feeding during the past winter. These were sold at approximately 45s. per qr. (equal to 15s. per cwt.). On this basis the dried whole acorns should be worth 12s. per cwt. (the kernels constitute approximately 80 per cent. of the whole dried acorns). Fresh acorns contain about 50 per cent. of moisture, which is reduced to 12 to 14 per cent. on drying. The value of fresh acorns should therefore be 7s. 6d. per cwt. A bushel of acorns weighs about $\frac{1}{2}$ cwt., so that 1s. per bush. would not be an excessive amount to pay for gathering. Drying the acorns presents the greatest difficulty. Small quantities could easily be dried in a hot-air cupboard or oven; larger quantities might be dealt with in a malt kiln or hop oast.

The conclusions arrived at may be given as follows:—

1. There is no apparent reason to suppose that acorns after proper drying contain any substance harmful to poultry.
2. Dried acorn kernels can be fed to poultry up to 2 oz. per bird per day without injurious results, provided the remainder of the ration is properly balanced.
3. Acorns possess considerable feeding value, comparable with a mixture of oats and maize.
4. It appears quite possible that grain can be completely replaced by acorns in the feeding of poultry for egg production, provided that the slight deficiency in protein is made up in the remainder of the ration.

THE following Note has been communicated by Dr. Thomas Milburn, Secretary of Agriculture to the Lancashire County Council:—

**A War Time Food-
Production Effort
in Lancashire.**

In May, 1917, the Wigan and District Executive Committee drew the attention of the County War Agricultural Executive Committee to several hundred acres of the Wrightington Estate which was lying derelict. The land was subsequently inspected by the Executive Officer and the Board's Commissioner, who reported that about 300 acres had been allowed

to run wild for about twenty years in order to serve as a fox covert; this portion was covered with a thick layer of decayed vegetable matter and with scrub consisting of hawthorns, elders and numerous clumps of rhododendrons. A further 200 acres was reported to be poor grass land which had been mown repeatedly and had had very little manure applied to it. The soil was reported as well drained, deep, and, apart from the odd places where the drains had become choked, admirably suited for arable cultivation.

The agent to the Estate accompanied the Committee's officials over the land and gave all the information in his power, but when informed that the land must be put under cultivation he stated that the owner was not in a position to tackle it. Subsequently Messrs. Sumner and Leivesley, produce merchants, Ormskirk, were introduced to the owner. and within ten days an agreement had been entered into between them and the owner to rent the land for a period of five years.

The 200 acres of poor land, which had been mown regularly and was in consequence not covered with scrub, was ploughed with a three-furrow plough, subsequently disced with the tractor, drilled harrowed and rolled by horses. It was dressed with $\frac{1}{2}$ cwt. of sulphate of ammonia and $2\frac{1}{2}$ cwt. of superphosphate per statute acre.

As the method of dealing with the rough portion (about 300-400 acres) of land intended for potatoes may differ in some respects from the methods adopted elsewhere with similar land, it appeared to the writer desirable that this method should be placed on record. The trees which were up to 8 and 10 ft. high were either grubbed by hand or pulled out by horses or tractors, and as much of the grass and roughage cut as was possible under the circumstances prior to the commencement of ploughing.

It was found impossible to obtain a set of steam tackle, and recourse was therefore had to the Government Titan tractors. From the outset considerable trouble was caused with the ploughs; the tractors themselves proved fairly satisfactory. The Executive Committee's idea was that the land should be skimmed with a three-furrow plough, but as it was somewhat late for skimming, and as Messrs. Sumner and Leivesley were averse to this method from the first, an effort was made to find a plough which would plough the land deeply and entirely cover the abundant vegetable matter which was on the surface. Many ploughs were tried, the most suitable being the Ransome single-furrow one-way balance plough with disc coulter, while

the Oliver and Grand Detour proved fair seconds. Ploughing with the Ransome single-furrow plough might appear to an outsider as somewhat laborious and costly, but in reality such was not the case, for the following reasons :—

1. A furrow 15 in. wide and 8 to 9 in. deep was taken, and so completely was the rough herbage covered that there was no growth on the surface in the spring.
2. The deep ploughing assisted drainage and the surface was left rough and exposed to the winter's frost. This made the land friable and facilitated operations in the spring.
3. The extra travelling of the tractor, with spuds fixed to the wheels, tended to break up the old sward and eventually flatten such rough grass as had not been cut.
4. A second ploughing operation, which would have been necessary had the land been first skimmed, was avoided—an important consideration in dealing with such a large area.
5. There were numerous groups of large timber and rhododendron clumps scattered about the land from a quarter to half an acre in extent, which it was neither desirable nor practicable to remove, and, as these were irregular in outline, the one-way plough was much more convenient for dealing with the angular and irregular shaped portions.
6. There was no waste of time in setting out ridges or making "finishings."
7. The surface was left even for subsequent operations.

It should be placed on record that a two-furrow balance plough was tried but proved unsuitable, but given a sufficiently strong plough there seems no reason why a two-furrow balance plough should not have done the work quite as effectively as a single-furrow balance plough.

Ploughing was commenced in June and finished in January. In March the tractors started the subsequent cultivation operations, which consisted of the following :—

- (a) Once disc cultivated.
- (b) Twice tine cultivated.
- (c) Once disc cultivated with harrows attached.

No praise is too high for the excellent work done by the disc cultivator.

The land was ridged by horses and the ridges set from south to north in order to allow the sun to penetrate between the haulms when grown. No farmyard manure was applied as it was considered that there was abundant fibre in the land. The following dressing of artificial manures per statute acre was sown broadcast over the drills prior to planting :—

Sulphate of ammonia	...	1½ cwt.	} Mixed before application.
Superphosphate	4 "	
Flue dust	3 "	
			Applied separately.

The cutting and planting of the sets was done by woman labour.

FIG. 1 —Condition of Land at the Commencement of Operations. Note the Amount of Rough Herbage.

FIG. 2.—Food Production Tractors and Drivers.

FIG. 3.—A Gang of Potato Planters.

FIG. 4.—The Potato Crop, as seen on 10th July, 1918.

It may be mentioned that there were eight tractors engaged on the work, 20 to 24 horses, 20 men and 30 to 35 women. Three to four hundred tons of seed potatoes were required.

The oats at the time of writing (15th June) are looking exceptionally well, and the potatoes look promising.*

To have brought this area into cultivation reflects great credit on the District and County Committees, and particularly on Messrs. Sumner and Leivesley. The action of this firm may be looked upon as a patriotic effort of no mean extent, especially as they ordinarily farm about 800 acres in addition to their large merchant business.

Whilst Messrs. Sumner and Leivesley pushed the County Committee at times for more tractors, there was a general absence of petty grumbling about shortage of labour, which seems to support the old saying that "Those who have much to do can do more and do it well." All that is required are the brains, capital, and, what is perhaps most important of all, the will to succeed in spite of the greatest difficulties.

THE following Notes are abstracted from the *Agricultural Organisation Society News and Notes*, June, July, and August, 1918 :—

**Successful
Co-operative
Societies.**

The West Midland Farmers' Association, Limited.—This society has a history extending over 16 years. With a turnover of

£118,000, and a membership of 792 (101 increase during the year), the committee is able to distribute £2,843 in bonus to members at 8d. in the £, to place £300 to special reserve for allowance to employees on Military Service, and to carry forward £1,210.

Biddulph and District Agricultural Society, Limited.—This society has increased its membership by 25 per cent. during the year. Its turnover has exceeded £15,000 ; its share capital has been increased, and the society has also acquired new premises with the object of extending its activities.

The South Devon Agricultural Co-operative Society, Limited.—This co-operative society was registered in May, 1917, but did not begin active business operations until September last. By March 31st, 1918, the membership was 182, and the share capital £853. The turnover for the six months amounted to £7,400. In addition to dealing in feeding stuffs, the society handled 55 tons of seed potatoes, notwithstanding difficulties

* Inspected August 2nd : Oats excellent ; potatoes about half excellent and about half has suffered from drought and other causes :

experienced in obtaining delivery—difficulties by no means peculiar to this society.

The Southern Counties Agricultural Trading Society, Limited.—The eleventh annual report of this society shows a turnover for the year of £540,000, an increase over the previous year of £181,000. Both the Trading Committee and the Auction Committee report an expansion of business, and the realised surplus for the year amounted to £9,681. The Mid-Hants Egg Depot has been taken over.

Ashbourne and District Co-operative Milk Producers' Association, Limited.—The report of this newly-established society only covers three months. The membership is 225. The turnover for the three months was £26,500, while nearly 100,000 gal. of milk were handled at the Mayfield Factory.

Co-operative Mill-Ownings.—The Wolverhampton and District Farmers' Association, Limited.—The annual report stated that there was a large increase in the business of this association. The mill which was purchased and taken over during the year had been a success, and is a real asset to the business. The net sales during 1917 amounted to £20,770, against £7,874 in 1916, whilst the membership numbered 162 at the end of 1917, as compared with 108 in 1916. The membership has since gone up to 197, and new members are continually being enrolled. The Dairy and Cheese Department is making good progress, and a considerable quantity of milk is being dealt with.

The Pershore Co-operative Fruit Market.—The sales for last year amounted to £81,857, being an increase of £35,903 over the previous year, while the profit realised was £3,042. The committee were enabled to recommend a bonus of £3 15s. per cent. to shareholding growers in proportion to the value of their produce marketed.

The Hayling Island Farmers' Co-operative Society.—This is a co-operative implement society, owning its own machinery, steam ploughs and cultivators. Of the thirteen farmers in the island eleven are members. The whole of the threshing is done by the society's tackle, and the committee is now contemplating the purchase of a tractor. The Secretary states that so far as getting the work done is concerned, the society's machinery has given great satisfaction, and no members would think of reverting to the old order.

The West Glamorgan Farmers' Association, Limited, reports a turnover for the last year of £9,077, an increase of over £3,000 on the preceding year, while the membership has risen from 112 to 158. Notwithstanding the difficulties of trading, the

profit for the past year was upwards of £200, and the association has accumulated a reserve fund of £366, mainly invested in War Loan, while members individually have bought War Savings Certificates to the amount of £3,232.

The Mid-Cheshire Farmers' Co-operative Society, Limited, shows a turnover of £62,840, with a realised surplus of £831. During the year the committee purchased a shop and mill at Chelford for use as a store, and they are well satisfied with this extension of the society's work.

Bishop Auckland Farmers' Association, Limited, reports a large increase in business during the year, the turnover being £20,120 as compared with £12,726 for the previous year. The profit for last year amounts to £435, and the report states that the purchasing of members' produce for re-sale is increasing rapidly.

Newport (Salop) and District Agricultural Co-operative Trading Society, Limited, has a membership of 453, a slight increase on the year. It has sold the produce of its members to the extent of 10,524 bags of barley and 8,477 bags of wheat and oats, and a very good business has also been done in clover, grass and root seeds. The turnover for the year was £101,601; a record for the society.

(1) **Obligations under Order and Penalties.**—Under the Parasitic Mange Order, 1911, every person in Great Britain having in his possession or under his charge a horse, ass, or mule affected with or suspected of parasitic mange is required to give notice of the fact with all practicable speed to the Police. Failure to give such notice renders a person liable to a fine of £20, and, in certain circumstances, to a month's imprisonment.

(2) **Prevalence of Disease.**—The information obtained by the Board from inquiries made in connection with the many outbreaks of mange reported to local authorities shows that the disease is very prevalent at present, and, though the disease is not of a nature which need alarm horse owners, it is highly desirable that every possible means should be taken to prevent animals becoming affected with parasitic diseases, and to cure them promptly if found affected.

(3) **Importance of Notification.**—One of the objects of requiring notification is to ensure that the affected animal shall be treated so as to be cured as quickly as possible. *The Order of 1911 as amended by the Order of 1918 permits of an affected*

animal being worked subject to certain conditions. An owner may also employ his own veterinary surgeon to advise him regarding treatment.

(4) **How Farmers Benefit Themselves by Observance of Order.**—It rests mainly with an owner to keep his horses fit and free from such parasitic diseases as mange and lousiness. By so doing he benefits himself, for the small extra trouble involved will pay him, since his animals will improve in condition, will be fit for more work, and will require less food than when their bodies are called upon to supply food for thousands of parasites in addition to their own needs. In treating the skin for one kind of parasite, others can be got rid of. It is not a very difficult matter to keep a horse free from parasites.

(5) **When in Doubt Notify Police.**—A farmer in his own interests will do well in all cases of doubt to obtain advice by notifying the Police. *He will then be informed whether the animal has mange or not, what form of mange, if any, it is suffering from, and how to treat it and prevent it from spreading to his other horses and those with which the affected animal may come in contact.*

(6) **Horse Owners Should be Suspicious when Symptoms Appear.**—At present it is as well to regard as suspicious every horse which shows signs of itchiness by rubbing, and particularly when the rubbing has caused areas where the hair is thin and broken.

Now is the time to get to work, as washing or spraying is a simpler matter in warmer seasons. Mange and lousiness can now be got rid of if owners give the matter a little attention.

(7) Horses belonging to the Food Production Department are under special rules for the cure and prevention of mange.

RULES TO BE FOLLOWED FOR THE PREVENTION AND CURE OF MANGE IN HORSES.

- (1) To aid in the prevention of mange, all horses should have their manes hogged and the long hair clipped from the feet and coronets.
- (2) As far as possible each horse should habitually occupy the same stall, and the harness of one horse should not be used on another unless it has been previously wiped over with anti-mange dressing, or otherwise disinfected.
- (3) Before another horse is put into a stall which has been occupied by an affected or suspected horse, the wood-work, head-rope or head-stall, and the floor should be washed over or sprayed with anti-mange dressing.

- (4) The harness, stable tools, and cart shafts used in connection with an affected or suspected animal should be well dressed with, or soaked in, the dressing, or they should, the case suiting, be placed in a small room and submitted for several hours to strong sulphur fumes. This should be carried out at least once every seven days, until the disease or suspicion has been removed.
- (5) When a case of mange is found to exist on premises, all the horses, their harness, etc., for purposes of prevention should be regarded with suspicion, the harness, stable tools, etc., being treated once a week as in (4). The skins of all horses, even though the animals show no outward symptoms of mange, should be sponged over or sprayed once a week (say, Saturday evenings) with anti-mange dressing, and particular attention should be paid to the coronets, the tail, and the mane. These should be well soaked with the dressing by means of a water brush or spray pump. Particular attention should always be paid to parts which appear to be rubbed. If the dressing be made up with warm water the horses will take more kindly to the spraying. After sponging or spraying of the skin the horse should be left alone for ten minutes, and then the skin should be wiped over to help drying.
- (6) If it be found after inquiry that the disease is sarcoptic mange an owner should get his veterinary surgeon to see the animal from time to time, and advise as regards treatment and progress. If it be found that the disease is psoroptic mange, an owner can quite well, after receiving the official instructions, apply the treatment to the animal himself; but it must be remembered that it is no use treating merely the parts visibly affected; the whole skin should be sponged or sprayed with the dressing prescribed.
- (7) The litter from an affected horse should be well moistened before removal. It should afterwards be placed on a manure heap well removed from contact with horses.
- (8) All new purchases or borrowed horses should be dressed or sprayed as in (5) at least three times.
- (9) For the prevention of external parasitism, which is prevalent in these times, and the infection of which may be picked up in innumerable ways, it would be well for owners of working horses, even when they appear free from parasites, to make a practice of spraying the

whole bodies of their animals once a week, say, on Saturdays, with a suitable anti-parasitic dressing. Suitable spraying machines and dressings can be obtained through agricultural implement dealers and chemists, but before placing their orders owners should apply for advice to the Local War Agricultural Committee, who are in a position to recommend the most suitable spraying apparatus and dressings.

NOTE.—Fuller and more detailed information regarding mange as a disease will be found in the Board's Leaflet No. 274. This can be obtained free of charge by applying to the Board of Agriculture and Fisheries, 3, St. James's Square, S.W. 1.

(NOTE.—*This article is also issued as Leaflet No. 8 of the Joint Committee of the Board of Agriculture and Fisheries and the Ministry of Food.*)

THE Board have received the following communication from Dr. Thos. Milburn, the Secretary of Agriculture to the Lancashire County Council :—

The "Crop" of a Wood Pigeon. Many examples of the damage done to newly-sown corn crops and to young clover plants have, from time to time, appeared in the Press ; the following will serve as a useful record of the voracious feeding of the wood pigeon, and will also show its preference for a vegetable diet, particularly grain and cultivated plants.

The pigeon was shot by Windham E. Hale, Esq., Chairman of the Lancashire Agricultural Sub-Committee and of the War Agricultural Committee ; the corn and other seeds were counted and have been preserved as a permanent record at the Agricultural Department, County Offices, Preston. The following is a list of the contents of the crop (see Fig.) :—

Barley grains	561
Clover leaves	113
Rye grass seeds	986
Clover seeds	108
Weed flowers	—

It was difficult to give a correct record of the weed flowers, as they were in various stages of development. There would, however, probably be about 60 to 80.

It will be noticed that grain preponderates both in bulk and weight, and as this grain had been picked up in an adjoining field which had been sown with barley, some idea of the loss sustained may be gauged when it is remembered that each grain should have produced its "hundredfold."

There were 113 clover leaves, each consisting of three leaflets, hence illustrating the considerable damage which must be done to young clover plants by wood pigeons.

The number of rye-grass seeds is very large and at least 80 per cent. of them would, if left, have produced living plants. The loss in crop must be considerable where large numbers of birds are concerned.

More clover seed might have been expected, but even 108 grains is a fairly large number for a single bird.

The weed flowers were exceedingly difficult to record as they were in various stages of development. They consist chiefly of charlock, and

108 Clover Seeds

Weed Flowers

986 Rye-grass Seeds

113 Clover Leaves

61 Barley Grains

as each flower head would, under normal conditions, have produced a large number of seeds it may be fairly said that these serve as a slight set-off to the damage otherwise done. Nevertheless there is overwhelming evidence that the evil is much greater than the good.

This is but the record of a single pigeon, and as hundreds of pigeons may be seen in a clover or grain field at once we can imagine what the sum total of damage may be. It is undoubtedly of such a nature that it is incumbent on farmers and others to reduce drastically the number of birds by every practical and lawful means available.

It should be recorded that there were no insects present in the crop of this pigeon, in fact no other contents besides those above recorded, except two pieces of grit.

DURING the present summer a good deal of rough hay has been cut from the roadsides with a view to its use for stacking or the immediate feeding of small stock. In some parts

Roadside Grazing. of the country also there has been a certain amount of roadside grazing, and it seems probable that this might be made much more general to the benefit of small holders and other persons of moderate means without serious danger to the public.

The attention of the Board of Agriculture has been called to the fact that in certain cases the police have intervened to prevent persons grazing their animals by the roadside in rural districts where there is plenty of grass not otherwise utilised and where there is no substantial risk of obstruction to users of the roadway. In doing this the police are no doubt entirely right from a legal point of view; but as the President of the Board of Agriculture has pointed out, and the Food Production Department now emphasises, in times like these a certain degree of latitude may well be allowed. As a rule the right of grazing on the roadside waste, unless it is part of the waste of the manor, and consequently "common," is vested in the owner of the adjoining fields; and if he chooses to do so he is entitled to prevent any use of it by others. But the action of the police above referred to does not appear to have had any connection with the protection of these interests; it seems to have been taken by way of enforcing the provisions of the Highway Acts, which impose penalties for the straying of animals on the highway or grazing on the roadsides, whether tethered or not. Mr. Prothero is of opinion that it is more important to-day that every bit of available food for animals should be profitably used than that the rights of ownership on the roadside should be rigorously enforced or the highway provisions literally interpreted. Of course, the assumption is that persons grazing their animals on the roadside will take care that no injury is done to the hedges, nor any obstruction caused.

The Home Office, it may be added, is in thorough agreement with the views of the Board of Agriculture on this subject, and a circular has been sent out to all chief constables of counties in England and Wales to this effect.

THE Report on the Elementary School Gardens of the Oxfordshire Education Committee for the year 1917, gives some very interesting figures of the work of school children in the cultivation of school gardens. The results speak highly of the efforts of our boys and girls in assisting in the great object of food production. Other Education Committees would do well to endeavour to emulate these excellent results.

The Report states that owing to changes in staff and other reasons it has not been possible to present as complete a return as it is hoped to do another year.

The total area under cultivation as School Gardens from which complete returns have been received was 6 acres in 60 places.

The vegetables produced from these gardens valued at Government market prices (as far as fixed), or at local market prices, were worth about £600. Thus every pole produced food to the value of 12s. 6d., and every acre to the value of £100.

Yields of the Green Crops.

Number of Reports Received.	Kind of Vegetable.	Variety.	Quantity of Seed Supplied to each School Garden.	Average Yield of Crop per School Garden.	School Garden with Highest Yield.	Total Yield of Crop from all the School Gardens.

67	Veg. marrows..	Long Green	18 seeds	" 33	Toot Baldon	" 5762
			18 seeds	" 35	Henley Trinity	" 2345

P.S.—The average area of each School Garden was 16 poles.

The seed potatoes supplied weighed 934½ lb., and produced a yield of 12 tons 4 cwt. 88 lb., on an area of approximately 89 poles. This gives an average yield per acre of 22 tons, and shows the great gain in yield resulting from spade cultivation. Peas yielded 2 tons 7 cwt. 34 lb. from 64½ pints of seed, onions 5 tons 5 cwt. 68 lb. from 73½ oz. of seed, carrots 8 tons 5 cwt. 90 lb. from 67½ oz. of seed, parsnip 2 tons 18 cwt. 23 lb. from 26½ oz. of seed, and turnips 2 tons 8 cwt. from 28 oz. of seed.

In addition to the above acreage the children have cultivated over 3 acres of waste land, and very large numbers of allotments and gardens belonging to widows and soldiers, voluntarily and without pay.

The yields of the green crops are given in the table on page 587.

OFFICIAL NOTICES AND CIRCULARS.

N.B.—The Orders which may be mentioned in this section of the JOURNAL may usually be obtained at the price of 1d. each from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, and 28, Abingdon Street, London, S.W. 1; 37, Peter Street, Manchester; and 1, St. Andrew's Crescent, Cardiff.

THE following Letters have been issued by the Food Production Department of the Board :—

Collection of Blackberries.

Letter (No. C.L. 37/4), dated 17th July, 1918, addressed to Horticultural Sub-Committees :—

SIR,—Owing to the partial failure of the fruit crops it is urgently necessary, in the national interests, to make provision for the systematic collection of blackberries and for the dispatch of the collected produce to jam factories controlled by the Ministry of Food.

Inasmuch as the responsibility for providing supplies of jam for the Navy, Army and civilian use rests with the Ministry of Food, it has been proposed by the Ministry that the responsibility for the distribution of the produce collected shall be entrusted to the Divisional Food Commissioner. Both this Department and the Ministry of Food are, however, desirous of securing the active assistance of the County Horticultural Sub-Committees in the organisation of collection in the counties and also of utilising the services of county marketing organisations for the purpose of dispatch of the produce collected.

In order that supplies of blackberries adequate to meet the very considerable needs of the situation may be collected it will be necessary to secure the active and full co-operation of all county organisations, as for example, the Women's War Agricultural Committees, Part-time Committees of National Service, Boy Scouts and Girl Scouts and Girl Guide Associations. In particular the help of the Local Education Authority, which proved invaluable last year, will be essential to success, and the Departments are approaching the Board of Education with the object of securing their approval of the suggestion that school teachers and school children should be asked through the Local Education Authority to lend their assistance.

In the event of your Committee being prepared to take a leading part in this work, I would suggest that you should communicate forthwith with the Divisional Food Commissioner with the object of holding a conference with him and others interested and, if necessary, appointing a special committee to work out details of organisation.

I am further to suggest that it would be desirable, if the work is undertaken by the County Horticultural Sub-Committee, that the Committee should appoint, for the purpose of this work, the Divisional Food Commissioner or the Officer to whom he delegates the work of blackberry organisation as a temporary member of the Committee.

Miss Day, the officer in charge of organising the collection of natural produce on behalf of this Department, will be pleased either to attend a meeting of your Committee, or, failing that, to send a detailed memorandum containing suggestions for the organisation of the collection in the counties.

I am, etc.,

(Signed) G. F. MIDDLETON,
For Controller of Horticulture.

Letter (No. C.L. 40/H), dated 31st July, 1918, addressed to Agricultural Executive Committees:—

SIR,—I am directed to inform you that the Food Production Department, at the request of the Ministry of Food, are asking the Horticultural Sub-Committees in various counties to organise the collection of blackberries throughout the country, as this fruit is urgently required by the Ministry of Food for the purpose of being made into jam to satisfy the needs of the Army and Navy. The Department have circularised the various Horticultural Sub-Committees with regard to the collection, and they have been asked to approach the Agricultural Executive Committees with a view to the latter asking farmers—

1. To allow reasonable access to the hedges surrounding their fields to any gangs of pickers who may be organised for the purpose; and
2. To refrain from clipping their hedges before the blackberries are gathered.

The Department will be glad if Executive Committees will assist the Horticultural Sub-Committees in this way so as to ensure that the maximum amount of blackberries in the county may be picked.

I am, etc.,

(Signed) G. F. MIDDLETON,
For Controller, Horticultural Division.

THE following Memorandum (No. C.L. 69/C. 1), dated 30th July, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board:—

Growing of Strawberries.

On 27th November, 1917, the Department issued a Memorandum (Ref. No. 7/C. 1)* to Agricultural Executive Committees suggesting that while it was not desirable to reduce the area under strawberries, Committees might take steps to restrict any increase, but the inquiries of the Department show that there has in fact been a considerable

* Printed in this *Journal*, December, 1917, p. 1012.

decrease in the strawberry acreage. Whereas the area devoted to this crop in England and Wales on holdings over one acre was 23,374 acres in 1914, there has been a progressive decline in each subsequent year, and it is estimated that the area at present does not exceed 10,000 acres.

The supplies from the present acreage are quite insufficient to meet the demand for jam both for the Navy and Army and for the civilian population, or to provide any surplus of fresh fruit. Moreover, as a result of the discontinuance of fresh planting during the War the majority of the remaining beds are old and worn out and will be grubbed as unprofitable at the present controlled prices. It is essential, therefore, that a considerable new area should be planted next autumn and spring, and the Department have decided accordingly to withdraw their Memorandum of 27th November, 1917, and to encourage replanting so as to secure an increase in the present area up to the acreage in 1914.

Agricultural Executive Committees should, therefore, let it be known that no objection will be taken to new plantations, but they may stipulate that they should be intercropped with a food crop during the first year after planting.

THE Food Production Department are anxious to secure, as soon as possible, information as to the results of breaking up grass land for this

**Inquiry as to the
Results Obtained on
Land Broken out of
Old Grass or Leys
of Five Years or Over
for the 1918 Crop.**

season's crop, and have asked Agricultural Executive Committees to obtain, during the interval between now and the end of the corn harvest, particulars regarding the crops growing on new arable land in their respective counties.

It has been requested of the Committees that a certain number of parishes in the county should be selected, and every field broken up for this year's crop in these parishes should be carefully inspected and an estimate made of the crop. The number of parishes will naturally vary in the different counties, but it should be approximately equivalent to one parish for every 5,000 acres of land broken up, and in no case should the number of parishes be less than three for an administrative county. The parishes are to be carefully selected, so that the average return from them may be regarded as fairly representative of the county as a whole. Where one of the officers of the Committee can be spared for the work and is accustomed to value growing crops, or crops in the stock, it is suggested that the most satisfactory plan would be to have all or most of the selected parishes surveyed by him in consultation with local farmers or surveyors, but in other cases district Sub-Committees might be asked to undertake the work themselves. They will have inspected most of the fields concerned, and will have had them under observation during the past year. Fields broken up in 1917 and summer fallowed last year are to be included in the return.

The estimated yield of each field inspected is to be recorded, and the returns, when completed, forwarded immediately to the Food Production Department, who will tabulate the results. It is intended that this estimate shall be checked during the winter by securing as far as is practicable the thrashing returns from the same parishes.

THE following Memorandum (No. 241/1 M. 12), dated 2nd August, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Organisation of
Threshing.**

In order in some measure to overcome the great shortage of engine drivers the Department suggest that Agricultural Executive Committees should approach corporations, district rural councils and other similar bodies with a view to arranging for the loan to threshing contractors of skilled engine drivers in the employment of local authorities. This proposal has been favourably considered by local authorities in certain counties, who have already been approached in the matter, and it is considered that every effort should be made to come to similar arrangements in each county.

THE following Notice (No. C.L. 225 (a)/M. 2), was issued in July by the Food Production Department of the Board :—

**Coal for Steam
Cultivation and
Threshing Purposes.**

Farmers who require coal for steam cultivation or threshing purposes should, in the first instance, apply for Priority Orders to the Food Production Department, either direct or through their usual coal merchants. If the coal merchants are unable to meet their requirements, they should communicate with the District Coal and Coke Supplies Committee covering the collieries from which their supplies have hitherto been obtained, who will in turn take the matter up with the collieries concerned. The District Coal and Coke Supplies Committees have been advised by the Controller of Coal Mines to this effect.

The Food Production Department only issue Priority Orders for coal for steam cultivation up to 25 tons at one time, and for threshing purposes up to 10 tons at one time. When farmers have only a few days' threshing it is advisable that they should arrange to share a truck.

It is essential that the instructions printed on the back of the Priority Orders are strictly carried out, and that the number of acres to be cultivated or of days' threshing to be done, is stated on the form. When a contractor is employed his certificate must also be given.

THE following Notice was issued early in August by the Food Production Department of the Board :—

**More Soldier Labour
for Harvest :
Important Notice to
Farmers.**

The Army Council has decided to release several thousand soldiers on agricultural furlough for harvest work. These men will be distributed among the counties where labour assistance for the harvest is most needed. Farmers requiring additional labour to gather the harvest should apply at once to their County Agricultural Executive Committee.

THE following Memorandum, dated 17th July, 1918, has been issued to Agricultural Executive Committees by the Food Production Department of the Board :—

Prisoners of War.

1. Until further notice it will not be possible for the Department to get prisoners of war voted by the Prisoners of War Employment Committee for new agricultural schemes, or additional prisoners for the existing prisoners-of-war camps. All prisoners of war who may be available will be allotted to schemes already in hand, or utilised in migratory gangs for harvest work. Further applications for permanent prisoner depots should, therefore, not be submitted to the Department for the present.

2. The attention of Agricultural Executive Committees is called to the fact that women of the Women's Land Army should not work on the same farm as prisoners of war. Committees should be careful to keep the Women's Committee informed of the farms to which prisoners are sent, in order that they may make their arrangements accordingly. Committees should not sanction applications for prisoner labour if women of the Land Army are being employed by the applicants.

3. *Harvest Wages.*—With reference to the scheme F.P. 295/L.2,* as to the employment of prisoners on harvest work, the War Office have not been able to agree to the mid-day meal being provided by the farmer, and they have informed all Commands accordingly. Rations to include the mid-day meal will, therefore, be supplied by the Military Authorities, and the Department have requested that the ordinary scale of rations laid down for prisoners should be increased for men employed for long hours daily on harvest work.

The following charges should be made for all prisoners when employed on corn or potato harvest work :—

7s. for a day of 10 hours, excluding meal-times, in the counties of Cambridge, Essex, Hunts, Isle of Ely, Lincolnshire, Norfolk, Soke of Peterborough, Suffolk, the East and West Ridings of Yorkshire, and Rutland, and 6s. for a day of 10 hours in the remaining counties of England and Wales. Overtime should be charged for at the rate of 8d. per hour.

4. The attention of the Department has been called to the fact that at some of the prisoner depots soldiers of Agricultural Companies have been attached for the purpose of taking out the prisoners, but do no work. Committees are apparently paying such men the ordinary rate of agricultural wages, but receiving no payment from the farmer in respect of their services. Committees should note that this is unauthorised, as all gang leaders must work and be paid for by the farmer. Soldiers who refuse to work or are incapable of doing so should be returned to the Distribution Centre, and other men sent in their places.

THE following Notice was issued towards the end of July by the Food Production Department of the Board :—

The Food Production Department draw
Badly-Laid Grain: attention to a useful device for the harvesting
How to Harvest It. of badly-laid grain crops. The method is commonly practiced in some districts, and consists of attaching a certain number of grain-saving guards or lifters

to the fingers of the knife board. These guards are simply enlarged fingers with self-adjusting points and, as a rule, four are required for a 5-ft. binder and five for a 6-ft. machine. Their cost is inconsiderable ; and in careful hands they prove of material assistance in the cutting of a laid crop. They are best adapted for ground that is not too soft. Local implement agents will, no doubt, be able to supply grain-saving guards.

THE following Notice was issued by the Food Production Department of the Board towards the end of July :—

**Crimson Clover and
Lucerne as Useful
Autumn-sown Fodder
Crops.**

The attention of farmers is directed to the importance of making adequate and timely provision for a supply of cattle fodder for next year.

Owing to the prolonged drought it is feared that in some cases young "seeds" have failed. On warm, loamy or medium soils in the southern and south-eastern counties failure, whether partial or complete, may be remedied by harrowing in seed of crimson clover (*Trifolium*) immediately after harvest at the rate of 15 to 20 lb. per acre, according to the degree of failure and the condition of the tilth. Crimson clover may also be sown on stubble land. The land should be heavily harrowed, not ploughed, the seed sown on the scarified surface, covered with lighter seed harrows and firmly rolled in. Normally the crop is ready for cutting or feeding off in the following May or June, or it may be cut for hay directly the flower-heads appear, or left until in full flower and made into silage. After the removal of the crop a half-fallow may be made, or in suitable circumstances a green crop taken. For ensilage, crimson clover might be tried as a substitute for vetches, which at present are both scarce and dear.

Lucerne is another useful crop suitable for early autumn sowing in certain districts. Though sown as a rule in spring, generally along with a nurse crop, there is sufficient evidence to show that on clean, well-drained land in the south of England, or milder localities further north, it will do equally well when sown alone before the end of August. In such circumstances it is generally taken after a bare or half fallow or after early potatoes. At least two cuts should be obtainable in the following year and up to four cuts each year subsequently. It may be fed green or used for hay or silage. Lucerne is specially valuable : (1) for supplementing bare pastures in dry seasons ; (2) as a means of economising oil-cake and supplementing roots in the winter feeding of cattle ; (3) on account of its power of enriching the soil for the benefit of subsequent corn crops.

For further particulars as to the cultivation and uses of these crops readers are referred to Leaflets No. 160 (*Lucerne*) and No. 182 (*Crimson Clover*), copies of which may be obtained free and post free on application to 3, St. James's Square, S.W. 1.

THE following Memorandum (No. C. L. 67/C.1), dated 23rd July, 1918, was issued to Agricultural Executive Committees by the Food Production Department of the Board :—

**Crops Damaged
by Insect Pests.**

In their Memorandum of the 24th May last (C. L. 56/C.1)* the Department authorised Agricultural Executive Committees to supply seed for resowing free of charge in cases where occupiers, who had ploughed up grass land by direction of the Committee, had suffered substantial loss from insect pests in spite of having taken all reasonable and proper precautions in the cultivation of the land.

When that Memorandum was issued it was uncertain whether the Defence of the Realm (Losses) Commission would admit claims for compensation in cases of loss from insect pests, and the offer to supply seed for resowing free of charge was, therefore, made in the interests of food production so as to secure some production from the land on which the first crop had failed.

The recent decision of the Defence of the Realm (Losses) Commission which was communicated to Committees in the Department's Memorandum of 12th July (C. L. 64/C.1)† has altered the position, and the authority to supply seed free of charge is therefore withdrawn.

No further payments should be made under that authority, and Committees should supply the Department before the end of this month with a statement giving particulars of all cases in which Committees have made use of the authority. The name and address of the occupier, the cause of the damage to the first crop, the area affected and the cost and kind of the seed supplied or paid for should be given, and the statement should be accompanied by a certificate that in each case the Committee satisfied themselves that the loss had not been due to any negligence on the part of the occupier.

AN Order (No. 631), dated 7th June, 1918, was made by the Board of Trade to the effect that :—

**The Hay and Straw
Order, 1918.**

1. No person shall, without the permission in writing of the Controller of Horse Transport, feed any horse or permit any horse to be fed with hay, straw or chaff made from hay or straw, except as provided in this Order.

2. This Order shall not apply to horses falling within the Classes mentioned in the First Schedule.

3. Horses falling within the Classes mentioned in the Second Schedule may not on any day be fed with more than the quantity of hay, straw or chaff made from hay or straw prescribed for such horses.

4. Any person in possession of a horse or horses falling within the Second Schedule shall keep a record in writing showing (1) the number and class of horses kept by him ; (2) the total maximum daily ration authorised by this Order ; (3) the description and quantity of hay, straw and chaff fed to such horses each week ; (4) the description and quantity of all hay and straw purchased by him and the date of such purchase. Such records shall at all reasonable times be open to the inspection of an Officer of Police or any person authorised by the Controller of Horse Transport.

* Printed in this *Journal*, July, 1918, p. 475.

† Not here printed.

5. No straw shall be used for the purpose of bedding horses.
6. In this Order "Horse" includes a mare, gelding, colt, filly, pony, mule and ass; "Hay" includes clover.
7. This Order shall come into effect on 17th June, 1918.

FIRST SCHEDULE.

Horses excluded from the operation of this Order :—

- (a) Horses in the possession of the Army Council, the Admiralty, or the Air Board, or exclusively used for the purposes of the Army Council, the Admiralty, or the Air Board.
- (b) Horses maintained and used exclusively for agricultural purposes.
- (c) Stallions used exclusively for Stud purposes, brood mares, weaned foals and yearlings.

SECOND SCHEDULE.

Class of Horse.	Maximum Daily Ration of Hay and Straw Chaff.
(a) Heavy Dray and Cart Horses and Trotting Vanners	16 lb.
(b) Light Draught Horses and Light Trotting Vanners	14 "
(c) Other Light Horses and Cobs	9 "
(d) Ponies 14 hands and under	7 "

Note.—Correspondence with respect to this Order should be addressed to the Controller of Horse Transport, 7, Whitehall Gardens, S.W. 1.

THE following Memorandum (No. C.L. 230/M.4), dated 22nd July, 1918, has been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

Supply of Forage.

The Department have had under consideration the existing scheme for the supply of forage by the Army Service Corps for horses under the direct control of Agricultural Executive Committees as set out in Circular Letter 12 L.2* of the 24th December, 1917. The War Office have now agreed to the revised scheme of which details are given below.

Allotment Committees have been set up in the various counties for the purpose of disposing of all hay which is surplus to the requirements of the Military Authorities and the producer. The Agricultural Executive Committee must inform the Allotment Committee for their county of the total quantity of hay which will be required during the next twelve months on the basis of two tons of hay for each horse at present under their direct control. Horses on hire to farmers for one month or longer under Scheme "A" of F.P.92 will therefore be excluded from the arrangement. The Allotment Committee should be informed also of the amount of hay which it is desired to be purchased in each locality so that railway and road transport may be reduced to a minimum. The hay will be bought in the stack and the Agricultural Executive Committee must arrange for it to be cut and drawn, as required, by their own men and horses. The price of the hay will be the net cost price, and Agricultural Executive Committees will make payment direct

to the Forage Committee. In the event of the number of horses under the direct control of the Agricultural Executive Committee being increased beyond present strength, it will be necessary to obtain hay for them under the existing arrangement, by which Agricultural Executive Committees indent on the Headquarters of the Command in which their county is situated.

The Department require to be informed at the earliest possible date of the total quantity of hay which each Agricultural Executive Committee has requisitioned from the Allotment Committee under the new scheme.

The Department have under consideration the possibility of similar arrangements with regard to the supply of oats and oat-straw, with regard to which a further Memorandum will shortly be issued.

THE following Circular letter (No. C.L. 5/T.), and the accompanying Memorandum (No. C. L. 5 (a) T.), dated 3rd August, 1918, have been addressed to Agricultural Executive Committees by the Food Production Department of the Board :—

**Preservation of
Farmyard Manure.**

SIR,—In view of the shortage of artificial fertilisers, and the increased need for manure because of the extension of the tillage area, it is especially important at the present time that farmyard manure should be carefully preserved.

I am to suggest, therefore, that in any action which may be taken by your Committee in the direction of improving methods of farming, special attention should be given to securing reasonable care of farmyard manure, including liquid manure.

I am to enclose for your information a Memorandum on the Preservation of Farmyard Manure which indicates the most important points to which attention should be given.

I am, etc.,

(Signed) H. L. FRENCH,
General Secretary.

ENCLOSURE.

Before the War, farmers in the United Kingdom are estimated to have used about 27,000,000 tons of farmyard manure, containing about 185,000 tons of nitrogen; they used some 80,000 tons of nitrate of soda and 60,000 tons of sulphate of ammonia, containing together about 25,000 tons of nitrogen. There is a great loss of nitrogen from farmyard manure as at present managed, which competent authorities put as high as 50 per cent. in some cases. If the making and storing of the manure could be so improved as to add only 5 per cent to the nitrogen usually present when the dung is applied to the land, this saving would be equivalent to nearly 50,000 tons of sulphate of ammonia.

The following suggestions have been drawn up with the object of securing better conservation of the fertilising constituents of farmyard manure :—

1.—*Manure Made from Fattening Beasts.*—If this is made in covered yards it should be left under the beasts until it is wanted or until it is necessary to empty the yard. Defective roofing and spouting should be made good as far as possible, to avoid washing by rain.

If made in open yards the manure should as soon as convenient be hauled out and tightly clamped. The dung heap should be as compact as possible; spreading over a wide area should be avoided as it always leads to loss. The position of the clamp is determined mainly by considerations of convenience, but preference should be given to sites well sheltered from rain and the prevailing wind. The clamp gains considerably in value if rain is kept out; rain not only washes out useful constituents, but it encourages certain destructive changes in the heap itself. The mischief is not entirely repaired by collecting and using the black liquid draining from the heap, though this should always be done. So important is the sheltering of the clamp that steps should be taken to give as much protection as possible. A layer of earth, several inches thick, put on directly the clamp is made, soaks up much of the rain and prevents undue leaching; straw-thatched hurdles have also answered well, and are useful in protecting a half-finished dung heap.

The losses brought about by the destructive changes in the clamp are intensified during the summer months, and as far as possible summer storage should be avoided. Even in autumn and winter there is some loss in the clamp no matter how efficiently it is shielded from the rain. The most economical plan, where it is possible, is to draw the manure from the yards straight on to the land and plough it in at once. Unfortunately this method cannot always be adopted.

2.—*Manure Made from Dairy Cattle.*—This has usually to be thrown out daily. It should be well protected from the rain. The worst plan is that too often seen where the manure is thrown out of the cow-sheds and left exposed to weather, with the result that streams of black liquid flow away. A much better plan is to convey the manure to a dungstead provided with a liquid-manure tank.

Where there is no dungstead the manure may be hauled straight on to the meadows in the autumn, and on to the arable land during winter and spring. During the summer it should be built up into a clamp, sheltered if possible from the sun. Special care should be taken of the liquid manure draining from the cow byres, as this contains valuable fertilising materials. It should be run into a tank and applied when convenient to the land. It may go on to grassland at almost any time, and to arable land after the autumn and before the middle or end of May.

AN Order (No. 860), dated the 13th July, 1918, has been made by the Food Controller and contains the following main provisions:—

Caerphilly Cheese 1. This Order shall apply to all Caerphilly
(Requisition) Order. Cheese manufacturers in Great Britain on
1918. and after 29th July, 1918.

2. Every person who in Great Britain manufactures any Caerphilly Cheese to which this Order applies shall place all such cheese at the disposal of the Food Controller, and shall deliver the same to such persons and in such quantities and at such times as the Food Controller may from time to time prescribe by directions under this Order.

3. Pending any such direction no person concerned shall dispose of any such cheese, whether in pursuance of any contract or otherwise, and shall take such steps as may be reasonably necessary to preserve such cheese in good condition.

Note.—All correspondence with respect to this Order should be addressed to the Secretary, Ministry of Food (Cheese Section), New County Hall, London, S.E. 1.

Makers whose cheese is requisitioned will be required to deliver their cheese to the Food Controller through a factor nominated by them and approved by the Food Controller. The official forms of nomination should be in the hands of makers before the 19th July, 1918. Any maker who by that date has not received an official form of nomination should at once communicate with the Ministry of Food.

A GENERAL Licence (Order No. 861, 1918) has been issued by the Food Controller under the British Cheese (Requisition) Order, 1918

**The British Cheese
(Requisition)
Order, 1918, and the
Caerphilly Cheese
(Requisition)
Order, 1918:
General Licence.**

(No. 578*), and the Caerphilly Cheese Requisition Order, 1918 (No. 860†), authorising every person from whom cheese is requisitioned under either of these Orders to continue until further notice to consume in his household, and to supply to his employees, and, in the case of a cheese factory, also to suppliers of milk to that factory and to the employees of such suppliers of milk, cheese for consumption in the households of recipients only at the first-hand price for the time being in force, provided that fortnightly returns are made to the Secretary, Ministry of Food (Cheese Section), New County Hall, Westminster Bridge Road, S.E. 1, showing the total quantities of cheese disposed of under this licence during the preceding fortnight and the number of persons supplied, together with such further particulars as may from time to time be required. The General Licence, dated the 29th May, 1918, issued under the British Cheese (Requisition) Order, 1918 (No. 579†), is revoked.

By an Order (No. 884), dated 17th July, 1918, the Food Controller prescribes the prices set out in the following Schedule as the maximum first-hand prices in respect of the varieties of cheese therein stated.

THE SCHEDULE.

	Maximum First-hand Prices for Delivery.	
	Before 8th August, 1918, inclusive.	On and after 9th August until further Notice.
	Per lb. s. d.	Per lb. s. d.
Caerphilly, whole milk	1 5½	1 6½
Caerphilly, partially skimmed, i.e. containing at least 25 per cent. of fat in the dry matter ..	1 4	1 5
Caerphilly, wholly skimmed, i.e., containing less than 25 per cent. of fat in the dry matter ..	0 11	0 11
Any whole milk cheese not ex- ceeding 2 lb. weight uncut, other than Caerphilly	1 9	1 10

* Printed in this *Journal*, July, 1918, p. 492.

† See above.

‡ Printed in this *Journal*, November, 1917, p. 910; and January, 1918, p. 1140.

Maximum First-hand Prices for Cheese Manufactured.				
	Before 9th June, 1918.	On and after 9th June until 30th June, 1918, inclusive.	On and after 1st July, 1918, until 31st July, 1918, inclusive.	On and after 1st Aug., 1918, until further Notice.
	Per lb. s. d.	Per lb. s. d.	Per lb. s. d.	Per lb. s. d.
Ripened Stilton and Wensleydale (Blue) ..	1 7½	1 8½	1 10	1 10
Dorset hand skimmed (Blue)	1 2½	1 3	1 4	1 4½
" separated (Blue) ..	1 0½	1 0½	1 0½	1 0½
" " (White) ..	0 11	0 11	0 11	0 11
All other whole milk cheese	1 4	1 5	1 7	1 8
All other partially skimmed cheese (i.e., cheese contain- ing at least 25 per cent. of fat in the dry matter) ..	1 0½	1 1	1 2	1 2½
All other wholly skimmed cheese (i.e., cheese contain- ing less than 25 per cent. of fat in the dry matter) ..	0 11	0 11	0 11	0 11

In all cases prices are *ex* Factory or *ex* Farm. All these prices are subject to the following terms :—

For cash within 7 days 2d. in the £ discount.

For cash within one month 1d. " "

As there is a shortage of cheese-making appliances, the Food Controller has arranged for the manufacture of wooden cheese-moulds in two sizes, for 56-lb. and 28-lb. cheese (Cheddar shape), at prices ranging from 27s. 6d. and 18s. 9d., respectively, downwards. Persons desiring to purchase moulds should apply at once to the Director of Milk Supplies, Section D.A., County Hall, Westminster, S.E. 1. The applications will be referred to such manufacturers as may at the time be best able to deal with them, and applicants will be advised of the action taken. Manufacturers will be entitled to require payment, at the price agreed with the Food Controller, on receipt of invoice. No remittances must be sent to the Food Controller. Persons requiring cheese-presses and vats are recommended to send to the Ministry (as above) copies of the orders which they lodge with manufacturers. (*National Food Journal*, 24th July, 1918.)

THE following Notice, dated 1st August, 1918, has been issued by the Board :—The Board of Agriculture and Fisheries have been officially informed that the tattoo marks on all pedigree horned stock exported to Argentina must be very clear, in order to prevent any difficulty in securing the entry of the animal in the herd-book of the Argentine Rural Society.

THE Board of Agriculture and Fisheries have been officially informed that live stock imported into the Republic of Ecuador must be accompanied by a certificate from a duly qualified veterinary surgeon in the country of origin to the effect that the animals are in good health and suitable for breeding purposes.

Export of Live Stock into Ecuador.

The certificate must be visé by the local Consul for Ecuador.

THE Report of the Board for the year 1917 of the Proceedings under the Diseases of Animals Act, the Market and Fairs

Report of the Animals Division of the Board for 1917.

(Weighing of Cattle) Acts, etc., has recently been issued. Copies may be obtained from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, price 3d. net., excluding postage. It contains an account of the work done during 1917 with regard to Foot-and-Mouth Disease, Anthrax, Glanders and Farcy, Parasitic Mange, Sheep-scab, and Swine Fever. The Report notes the large increase of animals attacked by Parasitic Mange and Sheep-scab, the returns for these two diseases during the year under review comparing unfavourably with those of the previous year. On the other hand there has been a decided fall in the numbers of cases coming under the other diseases mentioned above.

An account also is given of the consignments of animals shipped from Ireland to Great Britain. The Report includes a list of the Orders made by the Board under the Diseases of Animals Acts during the year, and a number of useful statistical tables.

AN Order (No. 886), dated 18th July, 1918, has been made by the Food Controller, fixing, with certain modifications and exceptions, the maximum prices for poultry and game. The

The Poultry and Game (Prices) Order, 1918. The prices given in the first column of the Schedule are for sales other than by retail, and those in the second column for sales by retail.

THE following Memorandum (No. C.L. 68/C. 1) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 31st July :—The question of taking measures to reduce the risk of loss by fire of farm produce has again been brought to the attention of the Department by the British

Fire Safeguards on Farms.

Fire Prevention Committee in a letter of which a copy is appended.*

Copies of the warning notice† were circulated to Executive Committees with the Department's Memorandum dated 1st August, 1917. Should any of the Committees require reasonable supplies of the notice, either for their own use or for distribution, application should be made to the British Fire Prevention Committee for the requisite number of copies, giving particulars of the use or character of distribution entailed.

Committees are also invited to consider the suggestions made for securing that the notice shall receive as much publicity as possible in their respective counties.

* Not here printed.

† Extract printed below.

EXTRACT.

THE following general hints have been issued by the British Fire Prevention Committee for the information of farmers :—

A.—FIRE PREVENTION.—1. Ricks.—Great care should be taken in selecting their position.

Prevention and Extinction of Fire on Farms. They should be placed alongside a *private* road in the fields so as to allow of easy access, and as far as possible from any public road or footpath. They should not be placed within 50 yd. of a railway line, or nearer than 20 yd. to a building with a chimney.

Space (where possible 10 yd.) should be allowed between each, to avoid as far as possible the risk of fire spreading.

Ricks should not contain more than 30 tons of hay or 10 acres of corn in straw. (Square-built ricks are preferable to circular ones.) After they are thatched in the sides should be carefully trimmed down, and all loose material removed as far as practicable.

2. Dutch Barns.—The use of these should be avoided if possible. If required, they should be covered with galvanised iron (corrugated) and have partially-protected sides, and should be built so as to allow a clear space of at least 10 yd. away from farm buildings, and between each other.

3. Loose Straw and Other Material round ricks and buildings should be frequently cleared up, more especially near any building where oil, paraffin, petrol, or any other inflammable matter is stored or used.

4. Burning Rubbish.—Any rubbish that has to be destroyed must not be burnt near any rick or thatched building, and in any case only on the lee side of any rick, if there is any wind.

5. Portable Engines.—Steam engines should have spark arresters, and the fire or ash boxes should be maintained in good condition. When the ashes are raked out from the fire-box they should be at once thoroughly wetted, and when the fire is banked the damper put on the smoke pipe.

Petrol and oil engines require care in starting, and any replenishing of fuel should not be done near artificial light or by any person smoking.

6. Spontaneous Combustion.—The danger of fire from spontaneous combustion in ricks, etc., is known—but some chemicals used as artificial manures are also liable to overheat or ignite spontaneously, such as nitrate of soda, superphosphates, and lime.

7. Naked Lights should be avoided everywhere, and only enclosed lamps or lanterns used. Where oil lamps are used, they should be trimmed and filled in a separate shed.

8. Smoking should be strictly prohibited near any rick or barn.

B.—FIRE EXTINCTION.—1. Water.—Where there is no water supplied at pressure from mains, a good well with pump to elevated store cisterns (with taps) should be provided.

2. Tanks constructed of brick cemented internally, or of concrete, placed in convenient positions, and supplied by rain water from eaves of buildings, are also of great service.

3. Buckets.—At least six galvanised iron buckets hung on hooks and kept filled with water for every rick or barn, and three additional ones to every two further ricks or barn in one group should be provided and placed in an open shed, or some other building which is available

both by day and night. These buckets should be painted red, and on no account be used for any other purpose.

4. Water Barrels.—Every farm should be provided with two or more portable water barrels and a large size "Brigade Hand Pump," or with a small "Garden Engine" on wheels. With either of these, a fire on roof or rick which cannot be attacked by buckets only, may be easily checked, and sometimes extinguished. Care should be taken, however, to see that the barrels and appliances are kept in good order and nearly full of water.

5. Ladders.—One light 30 or 35-round ladder and one 20-round ladder should be kept near buckets in shed and be always available for use.

6. Rick Cloths.—One large and one smaller cloth should also be kept where easily available, and should be placed on the ricks or thatched buildings in danger from fire, and water thrown on them by means of hand-pumps or buckets to prevent the fire spreading thereto.

7. Other Appliances.—Three or 4 cutting knives, 2 or 3 dung drags, 6 to a dozen stable prongs, and about 40 to 50 yards of strong steel wire rope, with loops at end, for pulling ricks to pieces, should also be provided.

Hay knives, when not in use, should not be left stuck into a rick, but kept in some appointed place.

8. Fire Engine Facilities.—If the fire engine is to draw from a pond or shallow stream, a suitable position for the engine and a sump for the suction should be prepared.

Ponds and streams should be frequently cleared of mud. The latter may often be dammed at a convenient spot to conserve a supply of water. Where a running stream is not permanently dammed, steps should be taken immediately upon the outbreak of fire to collect a good head of water for the fire brigade on its arrival. Sacks of earth, sand, etc., will be found useful for this purpose.

Certain other directions are given, dealing with the way in which an alarm of fire should be given: the action to be taken in the event of an outbreak of fire on a farm; the setting of a watch and its nature; and the prevention of strangers from sleeping in barns. Copies of this "Warning" are provided where desired upon written application with postage to the offices of the British Fire Prevention Committee, 8, Waterloo Place, London, S.W. 1.

THE following Notice was issued by the Food Production Department of the Board towards the end of June:—

**Farmers and
Air Insurance.**

Farmers will do well to consider the desirability of insuring against damage by aircraft if they have not already done so. The likelihood of such damage being incurred may be greater or less at the present time than it was last February, when the Food Production Department advised farmers to insure*; but anyway it is not, and cannot in the nature of the case be entirely negligible. For example, in certain areas there is undoubtedly some risk of injury to crops or stock or buildings by our own aircraft, and this possibility has been keenly discussed at various places where farmers congregate, during the past few months.

* See this *Journal*, March, 1918, p. 1486.

It may be useful to agriculturists to be reminded that they can insure against all reasonable risks in return for very modest premiums, and that full particulars are obtainable at the War Risks Insurance Office (Aircraft Department), 33, King William Street, London, E.C. Farmers whose total property exceeds £500 in value can only claim compensation from the Government for damage by aircraft if the value in excess of £500 is insured under the Government Aircraft and Bombardment Insurance scheme. Farmers whose total property is under £500 in value—they are comparatively few—can claim compensation to the extent of the actual damage done to that property, whether the property is insured or not. Notice of damage must be sent to the Insurance Company if the property is either wholly or partly insured, and to the Air Raid Compensation Committee at 51, Palmerston House, Old Broad Street, London E.C., if it is not insured. The Defence of the Realm (Losses) Commission (to whom certain farmers seem to have made application) have nothing to do with these claims.

THE first and second meetings of the Central Advisory Agricultural Council (see p. 517 of this *Journal*) were held on the 16th July and 6th August last respectively, Lord Selborne presiding.

**Central Agricultural
Advisory Council.**

At the first meeting a report from Mr. Buckley, the Director of Milk Production, was read, and a short discussion followed. It was decided that the Council should come to no conclusion on this matter until the further inquiries which were then being made by the Sub-Committee of Major Astor's Committee on the Production, Utilisation and Distribution of Milk, had been completed.

The draft Grain (Prices) Order, 1918, was discussed, and as a result it was agreed : (1) that the Council make a representation to the Board of Agriculture, the Ministry of Food, and the Royal Commission on Wheat Supplies, that in its opinion actual producers of cereals should receive adequate representation on the Home Cereals Committee of the Wheat Commission ; and (2) that a deputation from the Council should wait upon the Home Cereals Committee on Thursday, 18th July, urging that the prices should be, wheat and rye, 80s. per qr. of 504 lb. in October, 1918, rising by 6d. per month till June, 1919 ; milling barley, 67s. 6d. per qr. of 448 lb. ; malting barley, 72s. 6d. per qr. of 448 lb. ; oats, 50s. per qr. of 336 lb. in October, 1918, rising by 6d. per month till June, 1919.

At the second meeting Mr. Overman submitted a report of the deputation from the Council to the Home Cereals Committee on 18th July, 1918. The question of this year's prices for cereals was further discussed, and Sir Charles Bathurst pointed out that the recent bad weather and consequent postponement of the harvest provided further reasons for increasing the prices. As in the course of discussion it appeared that several members were under a misapprehension as to the attitude and action of the Board of Agriculture in the matter, Sir Daniel Hall stated that Mr. Prothero had, in fact, awaited the advice of the Council before expressing the Board's opinion on the draft Grain (Prices) Order, and that a reasoned letter had since been sent to the Food Controller generally supporting the prices put forward by the deputation. Sir W. Roffey stated that the matter was still

under the consideration of the Food Controller, and that he could make no announcement at the moment.

It was agreed that representation on the Council should be granted only to societies which are national in character, and that where there is more than one such society formed for the same purpose it should only be granted to that which is substantially the largest. Representation was not therefore accorded to the British Berkshire Society or to the National Union of Allotment Holders.

Lord Selborne moved, seconded by Mr. Elder: "That the President of the Board of Agriculture be requested to communicate with all other Government Departments which fix the price of agricultural products, and to request them to give this Council an early opportunity of expressing its views before they proceed to fix such prices." This was carried unanimously.

General Morgan, Administrative Member of the Forage Committee of the War Office, who was present by invitation, made a statement as to the fixing of the prices for hay and straw by the Army Council. It was afterwards proposed that the Army Council be requested not to issue any order as to the price of 1918 hay until it had heard the views of the Council. An amendment was moved and carried: "That it be a recommendation to the Army Council from the Central Agricultural Advisory Council not to fix the 1918 price of hay below £8 per ton without previously consulting the Council."

It was agreed that the Council should point out the danger of storing large quantities of cake, especially undecorticated cotton cake, under the authority of the Ministry of Food, and it was suggested that limited quantities should be released to farmers, more especially dairy farmers. Mr. Wise made a statement as to the present position with regard to tonnage for feeding-stuffs and the conditions under which feeding cake is being stored by the Ministry of Food.

A representative of the Ministry of Food also made a statement as to the action which that Department propose to take for dealing with the 1918 potato crop.

On the question of the shortage of labour for the harvest, the Council passed a resolution that the President of the Board of Agriculture request the Army Council to allow as many soldiers as possible who are skilled in agriculture to be placed at the disposal of the farmers at harvest time.

THE Board of Agriculture and Fisheries have appointed a Committee to study the life habits of the honey bee, with the object of improving the conditions under which bee-keeping is carried on in England and Wales, and to investigate the epidemic diseases of the bee, more especially the disease or group of diseases which pass under the name of "Isle of Wight"

**Committee to
Study the Habits of
Honey Bees.**

Disease. The Committee consists of:—

The Master of Christ's College, Cambridge University (Dr. A. E. Shipley, F.R.S.).

Professor Punnett, F.R.S. (Professor of Genetics, Cambridge University).

Dr. G. S. Graham Smith, M.D.

Professor G. C. Bourne, F.R.S., D.Sc. (Professor of Zoology and Comparative Anatomy, Oxford University).

Professor W. Somerville (Professor of Rural Economy, Oxford University).

Mr. T. W. Cowan (Chairman of the British Bee-keepers' Association).
 Mr. G. W. Bullamore.
 Mr. J. C. Bee Mason.
 Mr. A. G. L. Rogers (Head of the Horticulture Branch, Board of Agriculture and Fisheries).
 Mr. R. H. Adie will act as Secretary.

It is proposed to undertake the study of healthy bees at Cambridge, and the investigations on "Isle of Wight" Disease at Oxford. The Committee would be glad to receive specimens of bees suspected of suffering from "Isle of Wight" Disease for examination and experiment. Communications on this subject should be addressed to Mr. Rogers, at 4, Whitehall Place, London, S.W. 1.

THE Food Production Department of the Board of Agriculture announce that they are offering ten scholarships tenable at the Horticultural College, Swanley, Kent, for a course of commercial horticulture of about 38 weeks' duration. The course will commence on or about 19th September.

**Swanley
Horticultural Course.**

Preference will be given to candidates over 21 years of age who are suitable by education and former experience for the positions of forewomen, managers, etc. *Accepted candidates will be expected to join the Land Army.*

There will also be a few vacancies for paying students who wish to attend the same course. Students who are desirous of paying for themselves can obtain full particulars as to charges, etc., from *The Principal, The Horticultural College, Swanley, Kent*. All applicants are asked to provide two testimonials and give the names of two references. Application forms for the scholarships can be procured from *The Women's Branch, Food Production Department, 72, Victoria Street, S.W. 1*. Application forms for students who are desirous of paying their own fees can be obtained from *The Principal, Horticultural College, Swanley, Kent*.

THE Board desire to correct an error which appeared in the Table of Prices, etc., of Feeding Stuffs on p. 329 of the *Journal* for June last. Under the heading *Compound Cakes*

**Notes on Feeding
Stuffs in July:
A Correction.**

the statement "Containing not less than 6 per cent. of oil and 20 per cent. of protein, £16 17s. 6d." is inaccurate; for the figure 20, the figure 17 should be substituted.

Hull.—Oswald Smith, farmer, Dunswell, on sales of adulterated milk, £75.

**Prosecutions of
Farmers, etc., under
Statutory Rules
and Orders.**

Petworth.—Arthur Standing, Brighton, was fined £45, with 5 guineas costs, for buying nine fat beasts outside a market; and John Gibbons Edgar, Stag Park, £5 for selling them. Notice of appeal was given.

Ramsgate.—Charles and Bernard Philpott, dairy farmers, on sales of milk to retailers, £168. The price charged was 1s. 7d., instead of 1s., per gal. The defendants pleaded that the difference had been credited to their customers after an ineffectual attempt to get the maximum raised.

NOTICE OF BOOKS.

British Pig: The Art of Making them Pay.—James Long (London: Chapman and Hall, 1918, 4s. net.).—The author in this work has set out the lines on which pig-keeping in this country might be made a larger and more profitable industry. He shows the great extent to which we have been dependent on foreign supplies for our bacon and hams, and claims that with better management pig-keeping could be made a more thriving home industry. The different kinds of British breeds are dealt with in an early chapter, which is well illustrated, while under the heading "Breeding and Management" is included information in connection with the sow, litters, weaning, selling to fatten, etc. In subsequent chapters, feeding, the functions of food, the small pig-keeper, the piggery and its equipment, slaughtering, bacon and hams, and the simpler diseases of the pig, all receive attention.

Rothamsted Experimental Station, Harpenden, Report, 1915-17 (Harpenden, 1918).—The Report of the Rothamsted Experimental Station for the period 1915-17, with a Supplement to the "Guide to the Experimental Plots," containing the Yields per Acre, etc., has recently been issued. The main work of the Station is considered under four headings: (1) Economical Use of Manures and Fertilisers, (2) The Breaking up of Grass Land, (3) The Study of the Organisms of the Soil, and (4) Plant Nutrition Problems. A Report on Farm and Experimental Plots during the seasons 1914-1917 is also given, as well as tables of field trials, etc. A list of papers published by the Station, including soil problems, farmyard-manure, plant-nutrition problems, and technical papers, is also included in the Report. Copies may be obtained from the Director, Rothamsted Experiment Station, Harpenden, Herts, price 1s., including postage.

MISCELLANEOUS NOTES.

THE *International Crop Report and Agricultural Statistics* for July, 1918, published by the International Institute of Agriculture, gives particulars concerning the production of the cereal crops of 1918 in certain countries in the Northern Hemisphere. *Wheat*—The production in Canada, United States, British India, and Tunis is estimated at 192,195,000 qr. in

Notes on Crop Prospects Abroad.

1918, against 158,803,000 qr. in 1917, or an increase of 21.0 per cent. *Rye*—The estimated production in Canada and the United States is placed at 9,900,000 qr. this year, or an increase of 32.6 per cent. compared with last year, when it amounted to 7,465,000 qr. *Barley*—The production in Canada, United States, and Tunis is estimated to amount to 39,007,000 qr. in 1918, against 32,666,000 qr. in 1917, or an increase of 19.4 per cent. *Oats*—It is estimated that the total yield in Canada, United States, and Tunis will amount to 195,038,000 qr. in 1918, against 207,068,000 qr. in 1917, or a decrease of 5.8 per cent. *Maize*—The production in the United States is estimated at 368,560,000 qr. this year, or practically the same as in 1917.

The condition of the crops in other countries on the 1st July, 1918, is given as follows (100 being taken to represent the average yield in the last 10 years):—*Wheat*—Denmark, 100; England and Wales, 103; Scotland, Ireland, and Sweden, 105; Switzerland, 98. *Rye*—Denmark, 100; Ireland, 105; Sweden, 103; Switzerland, 102. *Barley*—Denmark,

80; England and Wales, 98; Scotland, 95; Ireland, 115; Sweden, 98; Switzerland, 100. *Oats*—Denmark, 80; England and Wales, 95; Scotland, 90; Ireland, 105; Sweden, 98; Switzerland, 94.

France.—According to an official estimate, the condition of crops on 1st July was as follows (last year's figures are in brackets; 80=good, 60=fairly good, 50=mediocre):—Winter wheat, 72 (61); spring wheat, 63 (65); winter barley, 73 (63); spring barley, 59 (70); winter oats, 68 (60); spring oats, 57 (70); maize, 62 (71); rye, 73 (65); potatoes, 60 (76). Spring crops, however, have improved since the rains came and the final results for these crops may be better than is indicated by the above figures. (*Broomhall's Corn Trade News*, 6th August, 1918.)

Italy.—According to an official estimate the wheat crop for 1918 is given as 22,000,000 qr. against 17,500,000 qr. last year. (*Broomhall's Corn Trade News*, 30th July, 1918.)

Canada.—According to official returns the area sown to wheat in Canada amounts to 15,838,000 acres, against 14,755,850 acres last year; and to oats 13,784,000 acres, against 13,313,400 acres last year. (*The London Grain, Seed and Oil Reporter*, 19th July, 1918.)

Japan.—According to a report from H.M. Ambassador at Tokio, under date 20th July, the first estimates of the year's crops in Japan are (last year's figures in brackets):—Wheat, 3,720,000 qr. (4,200,000); barley, 4,836,000 qr. (5,460,000); rye, 4,712,000 qr. (5,000,000). (*The London Grain, Seed and Oil Reporter*, 2nd August, 1918.)

THE Crop Reporters of the Board, in reporting on agricultural conditions in England and Wales on the 1st August, generally refer to the beneficial effects upon the crops of the rains that set in towards the middle of July. The storms were often violent, and a certain amount of corn, especially among the heavier crops, has been laid by them; but the damage is small compared with the general improvement that has occurred since the drought was broken.

Agricultural Conditions in England and Wales on 1st August.

Wheat is a very healthy and satisfactory crop everywhere, and in no district is a yield under average expected; while in the great corn-growing districts of the east it is fully 5 per cent. above average. It is distinctly the best crop of the year, and the straw is generally of good length. Barley on the whole is a little under average; only in the south-western counties are normal crops reported. Oats have received more benefit from the rain than the other cereals, and a decided improvement in their prospects may be noted, although except in the south-west and Wales, the yield will probably prove under average, and the straw is generally short. Beans and peas are generally satisfactory crops, and the yield is expected to be about average; they are best in the eastern counties.

Potatoes have also been improved by the rain; they are uniformly vigorous and promising, and a yield over average is looked for, with very few exceptions. Few reports of potato disease have come to hand, and the crop may be, so far, said to be unusually healthy.

Turnips and swedes suffered considerably from the drought. The earliest sown are generally fairly satisfactory, but the later fields were badly attacked by fly, and generally failed, so that much resowing was necessary. With the rain, however, the crops made a good start, and they are now growing vigorously; but they are naturally very backward, so that in few districts is anything like an average yield expected.

Mangolds have in some districts made remarkable improvement with the rain, of which they stood in much need, particularly in the midlands and east; in others, such as the north and some southern counties, prospects are hardly as good as a month ago. Taking the country as a whole, an improvement is to be recorded, but only Yorkshire among the districts mentioned below expects an over average yield.

Hay which was cut in good time and got in not later than the early days of July, was secured rapidly and in excellent condition; but that which was cut later has suffered some damage from the continuous rains; this has affected the north more than the south, and meadow hay to a greater extent than the clover. The yield of the latter is probably just under average; but prospects for meadow hay have consequently deteriorated somewhat.

The rain has also been of advantage to the hops, which were short in bine, and suffered badly from insect attacks, which have been very prevalent this year. The western district shows the poorest prospects. The probable yield still remains as a month ago, viz., seven-tenths of an average; there being perhaps a slight improvement in the west and a slight deterioration in Sussex.

Prospects for orchard fruit are still very poor, and hardly a reporter mentions the probability of an average crop of tree fruit anywhere in the country. Of small fruit, there have been a few good crops of raspberries, currants, and gooseberries, but these are in the minority, and fruit altogether has been disappointing.

Pastures have become fairly full of grass again since the rain, after having been very bare; and live stock have begun to show a marked improvement in consequence; they are healthy and in satisfactory condition.

Labour, especially skilled and casual labour, is very deficient, but most of the work has been done with the aid of women, boys, and German prisoners.

Summarising the returns, and expressing an average crop by 100, the appearance of the crops on the 1st August indicated probable yields per acre which may be denoted by the following percentages; Wheat, 104; barley, 98; oats, 97; beans, 100; peas, 98; potatoes, 102; mangolds, 95; seeds hay, 99; meadow hay, 95; and hops, 70.

THE following local summaries give further details regarding agricultural labour in the different districts of England and Wales:—

Northumberland, Durham, Cumberland, and Westmorland.—Skilled and casual labour is extremely scarce, although the shortage is less acute in some districts; favourable weather conditions have eased the situation somewhat.

Lancashire and Cheshire.—Labour is everywhere deficient and casual workers are difficult to obtain.

Yorkshire.—The usual skilled male labour is now almost unobtainable, but the work is kept fairly well in hand by substitutes.

Shropshire and Stafford.—Conditions remain very much the same. All labour is scarce, and it is difficult to get hoeing done, but, with the help of soldiers and women, work has been so far kept in hand.

Derby, Nottingham, Leicester, and Rutland.—Skilled labour is deficient, but the work is being done, more or less efficiently, by substitutes.

Lincoln and Norfolk.—The usual skilled labour is deficient, but the immediate need is being met by substitutes.

Suffolk, Cambridge, and Huntingdon.—Labour is still very scarce, but sufficient to keep necessary work in hand.

Bedford, Northampton, and Warwick.—The usual labour is deficient, but the work has been kept in hand by substitutes.

Buckingham, Oxford, and Berkshire.—Though the supply of labour, especially skilled, is deficient, great assistance has been rendered by soldiers, women, and German prisoners, and the work has generally been got through satisfactorily.

Worcester, Hereford, and Gloucester.—The supply of labour is short, but much assistance has been given by war agricultural volunteers.

Cornwall, Devon, and Somerset.—Labour is very short, especially skilled hands, and farmers are becoming anxious about the labour required for hoeing the roots and getting in the corn. Help is being given by women and German prisoners.

Dorset, Wiltshire, and Hampshire.—Labour is scarce, and few casual workers are available for turnip hoeing. Assistance is being rendered by women, boys, and German prisoners.

Surrey, Kent, and Sussex.—Labour is generally short, but assistance has been rendered by women, soldiers and German prisoners.

Essex, Hertford, and Middlesex.—Conditions are much the same as last month, and the shortage is being fairly well met. Wages still tend to increase.

North Wales.—The supply of labour is deficient, but generally, with the assistance of temporary labour, most of the work has been got through, though roots would sometimes benefit with more attention were additional labour available.

Mid Wales.—The supply of labour is deficient in all districts, but the shortage is less felt in some districts than in others.

South Wales.—Labour is scarce and temporary help often inefficient, but so far the necessary work has been accomplished.

THE following statement shows that according to the information in the possession of the Board on 1st August, 1918, certain diseases of animals existed in the countries specified :—

Prevalence of Animal Diseases on the Continent.	<i>Austria (on 26th June).</i> —Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.
	<i>Denmark (month of May).</i> —Anthrax, Swine Erysipelas.
	<i>France (for the period 16th June—6th July).</i> —Anthrax, Black-leg, Foot-and-Mouth Disease, Glanders, Rabies, Sheep-pox, Swine Erysipelas, Swine Fever.

Holland (month of June)—Anthrax, Foot-rot, Swine Erysipelas.

Hungary (on the 26th June).—Foot-and-Mouth Disease, Glanders and Farcy, Sheep-pox, Swine Erysipelas, Swine Fever.

Italy (for the period 1st—6th July).—Anthrax, Black-leg, Foot-and-Mouth Disease (1,435 outbreaks), Glanders, Sheep-scab, Swine Fever, Tuberculosis.

Norway (month of June).—Anthrax.

Sweden (month of June).—Anthrax, Black-leg, Swine Fever, Swine Erysipelas.

Switzerland (for the period 17th—23rd June).—Anthrax, Black-leg, Swine Fever.

No further returns have been received in respect of the following countries : Belgium, Bulgaria, Germany, Montenegro, Rumania, Russia, Serbia, Spain.

THE JOURNAL OF THE BOARD OF AGRICULTURE

Vol. XXV. No. 6.

SEPTEMBER, 1918.

EDITORIAL NOTES.

QUESTIONS relative to the economic production of beef and to the most suitable time at which cattle should be sold for slaughter are of very considerable importance.

Beef Production. Many authorities have long been convinced, in part from observation and in part from experimental results, that beef cattle generally are fed too long, are given an unnecessary quantity of concentrated food, and are fattened to an extent which constitutes a national economic loss. In this *Journal* for August appeared an account by Professor Wood of feeding trials which showed that many cattle are given much more cake than is really necessary to secure good results. Figures were given showing that on a low cake ration last year 178½ lb. of cake resulted in the production of 655 lb. of meat. In the Norfolk experiments of 1896-9 with a ration of 8 lb. of cake per head per day, 1,064 lb. of cake produced only a further 66 lb. of meat. The figures show that the decrease in cake consumption from 8 lb. to 1½ lb. per head per day only reduced the live weight produced by 3.3 per cent. and the meat by 9 per cent., whilst, taking the point of view of profit, for each extra pound of beef produced 13 lb. of cake, costing about 2s., was consumed. The article generally indicates a low cake ration rather than a high one.

In the present issue of the *Journal* (p. 623) appears a paper on Beef Production by Messrs. Mackenzie and Marshall which deals with problems relating to the most economic condition at which cattle should be sold and the best means by which that condition can be ascertained. It is shown that as compared with the production of "baby" beef, it is not an economic policy to fatten 2½-year-old bullocks; that there is

more waste in consumption of "fat" beef than in the case of beef from so-called inferior animals, and that while waiting for an animal to become what we have been taught to look upon as "prime" we may allow a total loss of 9 lb. of good meat every month of the animal's life so as to get part of the carcass as very fat meat and the rest as dripping. It is held that at the present moment far too many beasts are left unslaughtered until the most economic time for killing has passed and the beasts' usefulness has diminished. The fattening of the older animals to produce "prime" beef leads to the laying on of fat at the expense of meat production. Economy in beef production may best be secured by growing "baby" beef, though this may be difficult to carry out on farms which do no rearing but depend upon the winter feeding of bought stores. All who are interested in the production of meat should read very carefully the article by Messrs. Mackenzie and Marshall.

* * * * *

ELSEWHERE in this issue (p. 641) will be found a report of the Official Seed Testing Station, which was opened on the

14th November, 1917.

Seed Testing. The use of pure seed of high germinating capacity has always been important, but is specially so at the present time as one of the chief means of ensuring good crops. The results of the seed testing conducted at the official station are of special interest to both farmers and seedsmen, who will find in the report a detailed review of the results obtained in the season (8½ months) ended 31st July last.

Two leaflets which are of particular interest to farmers are Leaflet No. 297 (*Seed Testing*) and Food Production Leaflet No. 47 (*Testing of Seeds Order*, 1918).

* * * * *

MUCH has been written on the somewhat vexed question as to whether certain wild birds are useful or harmful to agriculture and horticulture. It may be regarded

Food of Wild Birds. as an undoubted fact that without very careful consideration and investigation of the food taken by any particular species, no trustworthy reply can be given to the question "Is this bird useful to agriculture?" A number of reports which have been published in recent years, though they may not be absolutely conclusive, may be held to give a very fair indication in the case of certain species. The report by Dr. Collinge published in this issue (see p. 668) deals with the food of the Missel Thrush, House Sparrow, Rook,

Skylark, Green Woodpecker, Sparrow Hawk, Kestrel, Wood Pigeon, and Lapwing. Of these Dr. Collinge concludes that the House Sparrow and Wood Pigeon are distinctly injurious, that the Rook and the Sparrow Hawk are injurious because too numerous, that the Missel Thrush is locally too numerous, and that the Skylark, Green Woodpecker, Kestrel and Lapwing are highly beneficial. The opinion expressed by Dr. Collinge that an investigation into the food habits of all the commoner species of wild birds is required, might well be supported by all lovers of birds, as no species should be generally condemned as harmful unless a thorough investigation has been undertaken.

* * * * *

It may truly be said that work on many farms would probably have come to a standstill had it not been for the labour of either skilled or unskilled women workers. The demand for women for all kinds of agricultural work, from threshing and potato lifting to milking and calf rearing, is larger than the number of women available, for farmers now recognise more clearly than a year ago the ability with which women can undertake certain forms of farm labour. Many notes have been published from time to time in this *Journal* (see also p. 716) dealing with the excellent work which the land women have done, including that large body of local women workers who have possibly not yet been enrolled in one of the recognised women's organisations. It is hoped that the next issue of this *Journal* will be largely devoted to a consideration of women's work in agriculture and horticulture, the majority of the articles being written by women who are devoting themselves to recruiting, organising and training women for the land.

* * * * *

IN view of the advantages which accrue from early sowing of wheat in a normal season, it is suggested that wherever the harvest operations will permit, wheat should be sown as early as possible. Late sowing appears to be frequently responsible for light crops. When seed is sown early the quantity sown per acre should be smaller; for example, $1\frac{1}{2}$ bush. per acre sown in September are likely to give as good a crop as 2 bush. sown in October or $2\frac{1}{2}$ bush. sown in November. The attention of farmers is specially directed to the note which appears at p. 717 and to the statement in the advertisement

columns, which refer to the high grade seed wheat which may be obtained through the scheme of the Food Production Department.

* * * * *

A MATTER which needs the attention of farmers immediately on the harvesting of the corn crops is that of the thatching of ricks. It is felt that this year it may be

Thatching. difficult for many farmers to ensure the thatching of their stacks in the usual way by fairly skilled thatchers, while the ordinary method of thatching is recognised by efficient farmers as being wasteful even if well done. Further, inefficient thatching and the consequent results due to the wetting of the ricks account for the loss of very large quantities of grain annually. A method proposed by Mr. John Hepburn, Southchurch, Essex, which he claims can be carried out effectively by comparatively unskilled labour, is therefore worth attention. In place of a straw thatch, Mr. Hepburn proposes the use of corrugated iron, Willesden board or weather-proof sheeting as a cover for the stacks, the materials used being held together by laths passing along it lengthwise. Stacks should be lean-to in shape, and built upon slabs of wood, each with an eyebolt, to which can be attached by means of a cord the laths which are used for keeping the roof in position. To the cord may be attached weights which serve to adjust the roof as the stack settles. The "fall" in the lean-to will vary naturally with the size of the stack. Mr. Hepburn has evidence that in very exposed country and very severe weather his method has proved thoroughly effective.

* * * * *

THERE has never been a time when it was not desirable to take the very greatest care that there was no wastage of manure on the farm. This is particu-

The Manure Heap. larly important at the present time, and for two reasons—(1) that all manure saved and applied to the land represents an increase in crop production, and (2) that there is a shortage of artificials. Farmers may very usefully take note of the suggestions on this subject which appear at p. 705.

* * * * *

THE Food Production Department recently referred to the fact that the most striking feature of the in-gathering of this year's harvest has been the general employment of the tractors, in conjunction with the reaper and binder. Apart from

Tractors and the Harvest.

any question of intrinsic cost there is no doubt that the work of the tractors in the harvest field has been invaluable, as it was earlier in ploughing grass land, in cultivating and other work. Special organisations for assisting farmers have been set up by the County Executive Committees, and the reports show that the work done by tractors in the harvest fields has been keenly appreciated. The Food Production Department state that in Somerset tractors cut nearly 1,000 acres of corn in a week, and in Nottinghamshire 760 acres. Once corn is ripe it can quickly be cut with the aid of tractors and safely placed in stook to dry before carting, the speed of tractor work being much greater than that of horse labour. Farmers will have long since recognised that in all branches of farm work the tractor has come to stay.

* * * * *

AN amelioration of the conditions governing English village life has long been desirable, and, indeed, essential, if a plentiful healthy rural population is to be retained

**The Village Clubs
Association.**

for agriculture. The workers of to-day look for something better than they have had—the land and all it means attracts them just as ever, but they need a wider mental horizon, communion with the world through books and the Press, more of the amenities of life, reasonable recreation, social intercourse, new ideas from mixing more freely with their fellow men and women, absence of patronage, a building up from below. In order to bring about something of this kind, to foster and set working the spirit implied, there has been formed the Village Clubs Association, the objects of which are to promote the establishment in rural villages throughout England and Wales of clubs founded upon the principles noted above, and to affiliate the clubs into one great organisation.

The Chairman of the Village Clubs Association is Sir Henry Rew, K.C.B., the Honorary Treasurers are Sir Charles Bathurst, K.B.E., M.P., and Mr. R. Holland Martin, C.B.; the Honorary Secretaries are Mr. A. Goddard, C.B.E. and Mr. George Dallas; and among the members are the Rt. Hon. R. E. Prothero, M.V.O., M.P. (*President of the Board of Agriculture and Fisheries*), Lord Clinton (*Joint Parliamentary Secretary of the Board of Agriculture and Fisheries*), and Sir A. D. Hall, K.C.B. (*Secretary of the Board of Agriculture and Fisheries*). The Committee appeal to all who are in sympathy with their objects to join the Association, and ask for subscriptions or donations,

which may be sent to the Treasurers at Martin's Bank, Lombard Street, London, E.C.

* * * * *

In the *Journal* for August (p. 589) appeared an official Notice dealing with the desirability of increasing the area under strawberries up to the acreage for 1914. Supplies of fruit

Fruit Growing. are always of the utmost importance, and with the present difficulty of importing fruit this year's failure of the fruit crops brings home to us very clearly the need for paying very special attention to home-grown supplies, and of increasing production as much as possible. In this connection correct and sufficient pruning, spraying, etc., are of very great value in ensuring a maximum production. Readers of this *Journal* will find many notes of interest touching on this subject (see also p. 706) while leaflets on fruit growing and fruit tree pests may be obtained free on application to the Board at 3, St. James's Square, London, S.W. 1.

* * * * *

ATTENTION is again directed to the desirability of collecting the maximum quantity of acorns as a food for stock, as they will serve to eke out short supplies of other feeding stuffs. An account of the food value of acorns as well as of beechmast

Collection of Acorns. is given in the Board's Leaflet No. 291, a copy of which may be obtained on application to the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1, post free. A full account of the food value of acorns, horse chestnuts and beechmast was given in this *Journal* for September, 1914, and notes giving instances of the feeding of acorns to live stock were published in October, 1915, p. 686, and December, 1917, p. 986.

* * * * *

A SECTION of this *Journal* which should be particularly useful to agriculturists, especially at the present time, is that including the various Notices, Circulars, and Orders (see p. 718), which should be valuable for the purpose of easy reference.

Official Notices and Circulars. Farmers should take particular note of matters which directly affect their interests, and should consult their County Executive Committee when in doubt as to their position. Difficulties which are not met by the Committee should be taken to the Food Production Department of the Board (72, Victoria Street, London, S.W. 1.).

BEEF PRODUCTION.*

K. J. J. MACKENZIE, M.A., and F. H. A. MARSHALL, Sc.D.

School of Agriculture, Cambridge.

INTRODUCTION.

OUR purpose in this article is to state in brief and summarised form the main conclusions we have arrived at as a result of an extended investigation upon beef production in this country. The problems, the solution of which we set out to obtain, arose primarily out of the War, and they relate to the most economical condition at which cattle should be slaughtered and the best means by which that condition can be ascertained.

Our results are of the most far-reaching character, and we are of opinion that they involve a considerable revision of agricultural practice in the matters to which they relate.

It is self-evident that in present circumstances it is vitally necessary for us, as a nation, to make the best use of our capacity to produce food. Moreover, of the food substances which enter into the diet of a normal man in a temperate climate, meat is usually one of the most important. This may be partly the result of habit, but it is indisputable that under conditions of abundant food supply those animals which subsist on a carnivorous diet are, physiologically speaking, at an advantage over herbivorous ones. Thus the dog, which feeds mainly upon flesh and converts it into flesh, is able to dispense with the gigantic alimentary compartments which are characteristic of the herbivorous horse, ox, or rabbit wherein the energy used in digestion is correspondingly large. Again, a dog can subsist on a restricted diet of lean meat so that all of it is absorbed, whereas the horse and ox, which are adapted for an herbivorous diet, pass daily an enormous quantity of fœces or undigested residue. In man roomy alimentary compartments do not exist, and a diet containing a moderate quantity of meat is an advantage, since its normal effect is to decrease the labour of digestion and to reduce the fœcal residue. The desirability, therefore, of maintaining our home-grown meat supply is a matter of the greatest national importance, from the point of view of keeping up the strength of our people and preserving in full measure their morale.

With a view to determine the most economic time for slaughter and how far the market judgment of a beast

* *Résumé* of a Report presented to the Board of Agriculture and Fisheries in April, 1918, by the Authors. The full Report will be printed later.

coincides with its actual yield of meat and fat, we collected, from week to week, a number of animals of different degrees of "ripeness" and weighed and slaughtered them under conditions of exact observation.

A detailed Report of our work was presented to the Board in April, 1918. The subject is divided below into four sections:—

- (1) Edibility.
- (2) The Most Profitable Condition.
- (3) Judging Beef Beasts.
- (4) Beeflings or Baby Beef.

The total number of beasts dealt with was 92. With one exception they were all steers. They included:—

18 Shorthorn Beeflings.	6 Hereford.
3 Lincoln Red.	3 Aberdeen Angus.
1 Half-bred Dutch.	2 Galloway.
30 Shorthorns showing 2 or more broad teeth.	6 Blue Grey.
2 Sussex.	4 Welsh.
4 Devon.	5 Red Poll and Red Poll Crosses.
	1 Shorthorn Heiter.

In the case of the beeflings we had the additional advantage of being acquainted with their complete life history and the way they had been fed, since they were born and reared either on the Cambridge University Farm or at the Lord Wandsworth Institution (Long Sutton, Hants). of which one of us (K. J. J. M.) is Agricultural Adviser and was, during most of the life of these animals, acting as Director of the Farm.

In an Interim Report* we gave instances of the chaotic state of knowledge and the remarkable faultiness of judgment shown by the trade. It is needless to emphasise further this part of the subject, for the results of the weighings of carcasses, obtained from animals handed over to unfortunate butchers under the grading system now in vogue, are only too evident testimony from all over England of the truth of the remarks we made about the general ignorance prevailing *when judgment had to be applied to the individual beast*.

It would be strange if it were otherwise, for in this country, beyond recording the prizes won at shows and the prices given for the winners, chiefly by foreign buyers, systematic work with beef-cattle has been confined, except as regards feeding trials, within almost negligible limits. It has consisted chiefly of recording a few weights and carcass percentages at the leading fat-stock shows. We ourselves

* Presented to the Board in August, 1917.

have for many years called in vain for opportunity to carry on such work, and yet two years and a half after the War began we had to start this inquiry without any of the equipment that is to be found in every agricultural establishment of repute in North America and in most of those on the Continent.

PROCEDURE.

Before dealing with the conclusions arrived at it will be well to give a brief account of our customary procedure.

Excepting for the beeflings referred to above and certain other steers which were obtained locally, the cattle were bought in the principal British markets, which were visited either by one (K. J. J. M.) or both of us. It was usually our purpose to obtain typical examples of the various breeds and types in the markets where they are best represented, and accordingly we attended public auction sales at Norwich, Cambridge, Newmarket, Leicester, Exeter, Shrewsbury, Wellington (Salop), Carlisle, Edinburgh, Perth and Dublin, other markets being also visited. Whenever possible we bought animals likely to afford suitable contrasts in regard to the degree of " ripeness " and, as we thought during the first stages of our inquiry, in regard also to percentage yield. In a few further cases steers were obtained for us by local agents in whom we felt confidence as having an expert knowledge of the beasts we required. Whenever possible a record of the beast's previous life history and the way in which it had been fed was procured from the original owner, and points of special interest were duly noted.

The beasts after being bought were conveyed to the University Farm, and were subsequently examined by one of us (K. J. J. M.) point by point. As a result of the examination the yield percentage (carcass to live-weight) was estimated. The following is a list of the points examined :—

- | | |
|---|-------------------------|
| (1) Neck vein. | (8) Loin. |
| (2) Chest and bosom or brisket. | (9) Flank. |
| (3) Chine or over shoulder. | (10) Hook. |
| (4) Shoulder blade and point. | (11) Rump. |
| (5) Crops or behind shoulder or over heart. | (12) Pin or aitch-bone. |
| (6) Behind elbow. | (13) Buttock. |
| (7) Lower rib., <i>i.e.</i> , floating or wing rib. | (14) Round or twist. |
| | (15) Cod or scrotum. |
| | (16) Thick flank. |

At the time of the examination other matters of interest or importance were recorded, *e.g.*, the state of the hide, the age as determined by the teeth, and the general condition of the animal.

The live-weight of each beast, both unfasted and fasted, was ascertained. In the case of our second series of animals (Nos. 50 to 92 in our Report) great care was taken that the beasts should be fasted for as near as possible 24 hours (the exact time being put on record) before ascertaining their fasted weight, but in the first series (Nos. 1 to 49) the time of fasting was sometimes rather varied. It was found that the difference between fasted and unfasted live-weights might be as much as 12 per cent. and was frequently 7 per cent., the average with our second series being 6.66, whereas Lawes assumed this loss to be usually about 5.5 per cent.

The beasts were slaughtered on the premises of a local firm of butchers,* and one, or more frequently both of us, were present. Observations were made on the amount of internal fat, and on the condition of some of the more important organs, and any other matter of interest was noted.

One of us (F. H. A. M.) was present also when the "sides" of each beast were cut up in the butcher's shop. Joints were taken from each animal (with a few exceptions), these being the 7th or middle rib and the 13th or wing rib (together with the first cut of loin). These were cut in as nearly as possible the same way and always by the same man, in each case, so as to make accurate comparisons between the different animals. Various measurements were made upon each joint so as to supply data as to the degrees of development of certain muscles and the relative amounts of lean and fat present. In the wing rib and first cut of loin the depth of flesh was also measured. The 7th rib was then submitted to analysis, the amounts of bone, cartilage, lean and fat being weighed and recorded. The central portion of the iliospinalis muscle (which extends from the neck back to the hindquarters, often called the "eye" of the joint by butchers) was carefully dissected out from the surrounding fascia and interstitial fat, the substance of the muscle was dried, and the intermuscular fat extracted. A portion of the same muscle from the wing rib and first cut of loin was treated similarly. It must be realised that the proportion of fat found represents the degree of marbling occurring in the muscular tissue. This was greater in the portion of *iliospinalis* in the 7th rib than in the meat taken from the same muscle in the region of the wing rib and loin.

The condition found in each "point," and the measurements

* We have to thank Messrs. Warrington, of Cambridge, for putting their slaughter-house and men at our disposal; without this accommodation it would have been impossible to carry out our inquiry.

of the joints, together with other data, are recorded for every individual animal in the Report in the hands of the Board. The records and measurements afford a useful "check" to the analyses, supplying, as they do, information upon the amounts of fat not only on the outside of the *trapezius* and the *latissimus dorsi* muscles, but also the interstitial fat which lay between the muscles and on the inner side of the ribs.

Joints from certain of the animals were subjected further to cooking trials and edibility tests. These were undertaken at the Cooking School of the King's College for Women under the direction of Dr. J. E. Lane-Claypon, and at the Munitions' Hostel at Dartford, where, through the kindness of Mr. Hudson and with the help of Mr. R. H. Glasspool, we were able to carry them out ourselves, assisted by the very efficient staff at the Hostel.

EDIBILITY.

In the reports on the results of the cooking trials undertaken at the King's College for Women it is shown that there was little discrimination between beasts of varying percentages as far as edibility and suitability for cooking and carving were concerned. Thus a beast of 51 per cent.* was favourably commented on, no distinction being drawn between it and another beast of 56 per cent. Again, the briskets of three beasts of 58.5 per cent., 57 per cent. and 54 per cent. were uniformly described in the report received from Dr. Lane-Claypon as "extremely good both as to flavour and general facility for carving." It should, however, be added that there was some evidence that where joints from beasts of low percentages were favourably commented on, these were ones with a proportion of fat which was high for their position as regards yield percentage, for, as will be shown later, the fat proportion and the yield percentage of a beast are not correlated in the way hitherto supposed.

The object of the inquiry undertaken by ourselves at Messrs. Vickers' Munition Workers' Hostel at Dartford was to ascertain precisely what proportion of the carcass from different beasts was actually consumed, and what was left as dripping, as bone, and as waste on the plates. As in our analytical work, we selected a particular joint as an indicator, and this joint consisted of the 8th and 9th (and in two cases also the 10th) ribs.

In the first trial two joints were compared, and about their appearance the expert staff of the famous catering department were in no doubt. One was pronounced to be first-class quality and the other to be inferior. Yet the results showed that the

* Percentages calculated on fasted live weight.

percentage of meat actually eaten was greater for the inferior joint, and notwithstanding that there was a larger percentage of scraps left on the plates used to serve the meat than was the case with the joint from the fatter animal. The scraps from the leaner bullock were chiefly composed of gristle, which yielded no dripping, whereas the plates used for the other brought back over 60 per cent. of fat, which was melted down into good, firm dripping.

In the second trial joints from three beasts were compared. Two were said to be entirely satisfactory in appearance. The third was pronounced to be very inferior; the extreme disapproval was, however, mitigated when the joint came out of the oven, and disappeared altogether on its being carved. The percentage of meat eaten from the "inferior" joint proved to be actually higher than that from one of the other two, and only very slightly less than the percentage eaten of the third joint.

The third trial is of special interest because it included two beasts the joints from which gave respectively the highest and the lowest efficiency yield as expressed by the percentage of meat actually eaten. The joint of highest efficiency was from an animal whose fat proportion (as indicated by the analysis of the 7th rib) was 27 per cent., which is very nearly the highest proportion of fat which can be obtained without a fall in the yield percentage (see below).

The trials included two beeflings, the joints from which were favourably commented on, and there can be no doubt that the slightly less degree of marbling sometimes found in baby beef animals of a given degree of fatness is compensated for by the increased succulence of this young meat.

The two series of trials demonstrate clearly that meat obtained from beasts of comparatively low percentage can be satisfactorily cooked, served and eaten (and without giving rise to any complaints) and with a minimal quantity of waste. In the case of young animals which are moderately well bred the meat from a carcass even as low as 51 per cent. can be eaten by the public without hardship, but it is no doubt easier to spoil a bad joint in the cooking than it is to spoil a good one.

THE MOST PROFITABLE CONDITION.

For the purpose of comparing the conditions of the various beasts we decided to analyse one joint from a large number of animals in preference to attempting an analysis of a few whole carcasses or large parts of carcasses. As already stated, the

joint we selected was the 7th rib, which by reason of its position in the body and on account of its containing cartilage, bone, lean and fat in well-marked proportions, we took as an indicator or sample of the carcass as a whole.

In the table which follows the beasts are divided into four groups according to their percentages (carcass to live-weight) : (1) under 53 per cent.; (2) 53 per cent. or over, but under 55 per cent.; (3) 55 per cent. or over, but under 57 per cent.; and (4) 57 per cent. or over; and the average composition of the 7th rib is given for the animals in each of the four groups.

*Table showing Average Composition of " 7th Rib " in
Beasts of Different Percentages.*

<i>Under 53 per cent.</i>				<i>53 per cent. or over, but under 55 per cent.</i>			
Cartilage	3.7	Cartilage	3.3
Bone	18.4	Bone	17.3
Fat	15.5	Fat	18.4
Lean	62.1	Lean	60.6
<hr/>				<hr/>			
99.7				99.6			
<hr/>				<hr/>			
<i>55 per cent. or over, but under 57 per cent.</i>				<i>57 per cent. or over.</i>			
Cartilage	2.6	Cartilage	2.4
Bone	16.9	Bone	16.0
Fat	21.5	Fat	24.4
Lean	58.4	Lean	56.9
<hr/>				<hr/>			
99.4				99.7			
<hr/>				<hr/>			

N.B.—Intermuscular fat (*i.e.*, marbling) is included in the lean in the above-given analysis—that is to say, it had not been separated out.

Each group contained about 20 beasts. It will be seen that there is, *on the average*, a certain correlation between the percentage of the animals and the amounts of bone, cartilage, lean and gross fat (*i.e.*, not including intermuscular or " marbled " fat) when the animals are divided in this way.

There was, however, a large amount of variation within the limits of each group. The difference may be due partly to age, breed and environment, but it is evident that there were wide individual differences which are difficult to interpret. This is shown in the next table, in which the beasts are arranged in the order of their fat percentage and are divided into four groups corresponding approximately but not exactly to the four groups in the preceding table. Here the yield percentage (carcass

to live-weight) of each individual is set out, and the average yield percentage for each proportion of fat is also appended.

Table showing Correlation between Percentages of Fat and Percentage of Yield.

Proportion of Fat.	Percentages of Yield of Individual Beasts.	Average Percentage of Yield.	Variation in each Group.
9	51	51	50 to 58
10	—	
11	51, 53, 51	52

24	60, 56, 58, 58, 56, 53	57	53 to 62
25	59, 58	58	
26	56, 55	55	
27	61, 58, 57, 58, 58	58	
28	62	62	
29	—	—	
30	57	57	
31	60, 56, 56	57	
32	—	—	
33	56	56	

It is seen, for example, that beasts with a yield percentage (carcass to fasted live-weight) of 56 may have a fat proportion of as low as 15 per cent. or as high as 33 per cent. It is also shown that the beast with the highest yield percentage had a fat proportion of only 28 per cent., and that all those with a greater amount of fat were beasts of lower yield percentage; in other words, that after a certain point is reached (namely, 28 per cent.), the increase in the internal fat (that is, the fat attached to the intestines, and mesenteries and other "offal") reduces the yield percentage.

In the tables* constructed by the late Sir J. B. Lawes for estimating dead-weight from live-weight it is assumed that

* "Tables for estimating dead-weight and value of cattle from live-weight," Published for the Authors by the Royal Agricultural Society of England.

there is a direct correspondence between the yield percentage and the proportion of fat. The beasts are divided into five groups as follows :—

							<i>Per cent.</i>
(1) Stores	50-51
(2) Fresh Stores	52-53
(3) Moderately fat	54-57
(4) Fat	58-62
(5) Very fat..	63-65

Our results show clearly that not only is this correspondence very inexact for beasts in any condition of fatness, but that for fat and very fat cattle it is directly contrary to fact.

Further, the proportion of fat present, as indicated by an analysis of the 7th rib, is very often in closer correspondence with the *estimated* yield percentage (carcass to live-weight) than with the actual percentage. Thus in 10 beasts having an error of plus 2 or over in the estimated percentage, 8 proved on analysis to belong to groups having a higher percentage of fat than that indicated by their actual percentage. Conversely, of 17 beasts having an error of minus 2 or more in the estimated percentage, 10 proved on analysis to belong to groups having a lower proportion of fat than that indicated by their actual percentages. It is noteworthy that the exceptions in both cases (that is, 2 in the first case and 7 in the second) all belonged to groups which their percentages indicated—that is to say, it *never happened* that a beast with an under-estimated percentage was found on analysis to have a *higher* proportion of fat than that indicated by its actual percentage, nor did an *over*-estimated beast ever have a *less* amount of fat than that indicated by its real percentage. This matter is referred to again below in the section on Judging Beef Beasts.

No attempt was made to draw conclusions as to the percentage composition of different breeds, since the amount of individual variation was found to be too great to warrant the deduction of definite results from the limited number of beasts dealt with, though we did find one breed which seemed particularly easy to over-estimate.

The next table shows the percentage of fat found in samples of the iliospinalis muscle taken from the 7th rib and the 13th or wing rib. These analyses show the amount of "marbling" present in the meat. This condition is often taken when present as an indicator of good, or when absent as an indicator of bad, quality in the carcass. The beasts are arranged in the same four groups as in the first table.

TABLE SHOWING PERCENTAGE OF FAT (i.e., "MARBLING")
IN PORTIONS OF IliosPINALIS MUSCLE TAKEN FROM
7TH RIB AND WING RIB RESPECTIVELY.

Under 53 per cent.				53 per cent. or over, but under 55 per cent.			
7th rib	11.8	7th rib..	12.9
Wing rib	6.4	Wing rib	8.6
55 per cent. or over, but under 57 per cent.				57 per cent. or over.			
7th rib	17.3	7th rib..	20.4
Wing rib	12.5	Wing rib	13.9

It will be seen that in both ribs the fat in the second group does not greatly exceed that in the first group, but that in passing to the third group there is a considerable rise (4.4 per cent. and 3.9 per cent.) in the fat proportion in the two ribs. In the final group the fat in the 7th rib has increased a further 3 per cent. and that in the wing rib 1.4 per cent. There was, however, much individual variation, the relation between the marbling and the gross fat being sometimes widely different in individuals of the same or similar degrees of fatness.

In view of the importance attached to marbling, the presence of which is generally recognised as adding to the value of meat from every point of view, these results point to beasts having an average yield percentage of 55 to 56, an average gross fat proportion of about 21 to 23 per cent., and the average amount of marbled fat in the 7th rib at about 17 or 18 per cent., as the most useful and profitable in any conditions approaching normality. *In present conditions steers might well be slaughtered when still less fat. One has to see the amount of waste fat on the intestines and hide to realise the full extravagance of feeding excessively, and this state of affairs we witnessed in the case of grass-fed animals, and very frequently, indeed, with beasts caked on the grass or finished in yards. These observations, and our own ascertained data, confirm the conclusion indicated by the result of all feeding trials, namely, that the fatter an animal gets the less return he gives for his food. They are in complete agreement, further, with the established fact that the longer an animal lives the more food he requires to put on weight. Both these factors have to be balanced with (1) the edibility of the carcass after slaughter and (2) the difficulty, trouble and expense of rearing the calf till weaned.**

* "Baby-Beef," by K. J. J. Mackenzie, *Journal of the Board of Agriculture*, Vol. XVII. (1910—11), p. 177.

JUDGING BEEF BEASTS.

Special Factors in the Determination of Yield Percentage.—In buying beef beasts it is obvious that total weight must always be the most considerable factor in determining the value of an animal, but owing to personal prejudice an undue importance is often assigned to weight in estimating a beast's yield percentage. Thus, good quarters play an important part in deciding live-weight, but there is no evidence that they contribute a greater share than the forequarters in determining the percentage. "Quality" is a source of deception as regards bone; the bony frame adds to the carcass weight just as does the flesh covering it, though the butcher does not want bone, and consequently looks upon the "strong" boned animal as of bad quality. Age has been much exaggerated as a factor in deciding the percentage, as our results show, for even beeflings may attain a yield of 58 per cent. The complete investigation shows, however, that out of 18 animals that had 5 or more broad teeth up (say, from 30 to 48 months old) only 1 yielded less than 54 per cent. The thickness of a beast's hide seems to have little practical effect on its percentage. Loss on fasting may play an important part in estimating. In 40 beasts with which we exercised special care in this matter the loss varied from 3 to 9.09 per cent., the highest actual loss being 112 lb. and the lowest 21 lb. The average loss for the 40 beasts was 6.66 per cent. The 20 beasts giving the highest percentage had an average loss of 6.21 per cent. and the 20 lowest an average loss of 7.12 per cent. on fasting.

We may now consider briefly the various points judged. A list of these points has been given above (p. 625). They may be grouped into (1) those governing the width of the beast's frame and quarter, (2) those governing the covering of the "neck vein" and "frame" (*i.e.*, all points in front of the "hooks"), and (3) those governing the covering of the quarter (including the flank).

- (1) Our figures show clearly that very great stress should be laid upon the value of width in estimating the probable percentage of carcass to live-weight. This is seen especially when considering the bosom or brisket (point 2) and the chine (point 3).
- (2) Of the points governing the covering of the frame (or the parts of the body in front of the quarter) the neck vein (point 1) is of great value in estimating the percentage. Of the other points the crops (point 5), the lower or wing rib (point 7) and the loin (point 8) are

very useful indicators. With regard to the effect of age on the covering of the frame it was found that the neck vein, the chine, the wing rib and the loin were of comparatively little value in estimating yearling cattle. The point (No. 6) "behind the elbow" or the butcher's "thin flank" differed from the others in that all the animals receiving the highest praise for covering were those showing two broad teeth.

- (3) Of the points governing the covering of the quarter, including the flank, our figures show that the hook (point 10), the pin or aitch-bone (point 12) and the *depth* of the buttock (point 13) are of considerable value as indicators. The round or twist (point 14) and the thick flank (point 16) are comparatively worthless. The flank (point 9) has a very high value set upon it by the practical man, but our results supply little evidence in support of this claim, though heaviness of flank seems to be a better indicator than thickness. The rump (point 11) does not seem to afford any great help to the estimator, notwithstanding that judges at fat stock shows pay great attention to this point. The cod or scrotum is of little value, and we have formed the opinion that the mode of castration affects the later development of this point. With regard to the effect of age upon these points it would appear that the rump, the hook, and the pin bone are all better indicators with older animals than with yearling cattle. Moreover, in the case of yearlings, thickness of flank is more important than heaviness.

Condition of Fatness.—It has been pointed out above in the section on "The Most Profitable Condition" that over-valuing of the state of fatness as a means of appraising yield percentage has been one of the main causes of inaccuracy in estimating. The results of this error may now be considered in relation to the present national necessity.

The public just now has need of every useful animal, *i.e.*, one that gives a good yield of carcass with enough fat. The error tends to leave a very large proportion of our cattle feeding too long because the estimator believes them to be low in yield of carcass, since the percentage of fat is only normal or "useful." He is, in other words, *waiting till he feels fat* on the animal, which will most likely produce a high percentage of dripping but *need not* necessarily give the nation a large amount

of useful meat. **The nation cannot afford to wait**; it wants all the cattle that are useful *immediately* they are ready and yield weight enough: to keep them longer is to use up food that is badly wanted for other purposes or to encumber land that should be under the plough or growing hay, much wanted for the winter's keep.

How far the error just referred to can be carried is well shown by two bullocks (Nos. 73 and 80 in the main Report). The former was an 8-tooth animal (2 only just through) that one of the first graziers in Leicestershire was just about to offer as "*prime*." We estimated it at 60 per cent. ("Fat" in Lawes' Tables). The latter, No. 80, was a beast off the University Farm which we kept back three months because we did not think it good enough to go with companions slaughtered at 15-16 months old. No. 73 was finished on the *best bullock land* in Leicestershire. No. 80 had a small amount of cake (3.5 lb.) to help out somewhat poor grass, from June to October. We slaughtered it then, much against advice given by good practical men for the *experiment*. We only estimated it at 53 per cent. (by Lawes' Tables "*Fresh Store*"), but it yielded over 56 per cent. The Edibility Tables show that only 47.7 per cent. of the joint from No. 73 and 48.8 per cent. of No. 80 was eaten up readily.

(No. 73.)				(No. 80.)			
Ascertained carcass per-				Ascertained carcass per-			
centage	56.2			centage	56.02		
Fat in joint percentage..	33.75			Fat in joint percentage..	15.68		
Carcass weight in stones				Carcass weight in stones			
(14 lb.)	56.2			(14 lb.)	39.0		
Age about 42 months ..	—			Age 18 months 24 days	—		
	stone				stone		
Carcass weight put on per	weight.			Carcass weight put on	weight.		
month of life	1.34			per month	2.05		
Calculated fat per month	.452			Calculated fat per month	.322		

From the above figures we see that while waiting for an animal to become what we have been taught to look upon as "*prime*" we have allowed a *total loss* of 9 lb. of good meat every month of one animal's life so as to get part of his carcass as very fat meat and the rest as dripping. *This, of course, is an extreme case, but the whole tendency of the misconception lies in this direction.*

In the same way the misconception above referred to may lead to over-feeding. Through the courtesy and the large-minded policy of the Trustees of the Lord Wandsworth Institution, who wished to help the inquiry from the resources of the

Trust, we are able to demonstrate the truth of our contention. The Trustees put at our disposal the joints from 12 beefing steers, the history of which we know. The four beasts (Nos. 33, 34, 51, 53, in our main Report) were all treated in the same way, as the results here set out :—

No. of Beef Beast.	Actual Carcass Weight.	Estimated Carcass Weight.	Percentage of Fat.	Age.	Milk Ration Fed to Calf.
	Per cent.	Per cent.			
53	53·88	51·0	15·08	13½ months	*10 gal. milk.
51	54·8	53·5	—	13 "	50 "
33	53·0	54·5	23·94	12 "	50 "
34	55·85	56·0	20·28	13 "	160 "
Average	54·882	53·75	19·76†	12·875	67·5

* Except that the amount of milk, when reduced, was replaced by calf meal substitute, the steers were all fed in the same way.

† Average of 3; 51 was not analysed for fat.

It will be noticed that the average carcass percentage is 54·88 and the average fat percentage is 19·76.

Believing that we should increase the carcass yield, we decided to imitate the local practice with beefings and have them forced at the end of their feeding time. The feeder was, therefore, instructed to "finish" with all the cake and corn which was readily eaten. The result is set out as follows :—

No. of Beef Beast.	Actual Carcass Weight.	Estimated *Carcass *Weight.	Percentage of Fat.	Age.	Milk Ration Fed to Calf.
	Per cent.	Per cent.			
90	53·69	51·0	18·59	14 months	10 gal. milk.
87	53·3	52·5	24·37	15 "	50 "
86	53·2	54·5	20·03	15 "	50 "
91	51·78	53·0	19·84	14 "	160 "
Average	52·99	52·75	20·7	14·5	67·5

It will be noticed that with these forced beasts the carcass percentage is *down* and the fat percentage is up. The number of comparable animals is, of course, small, but it must be admitted that the figures are at least strongly suggestive.

It might appear unbelievable that such a misconception as that above alluded to in regard to fatness as a guide to percentage yield could be universal, but there are explanations. To begin with, it had behind it the authority of Sir J. B. Lawes, whose name in *another department* of Agriculture is revered all over the civilised world for his investigations into

matters connected with manures and manuring. Further, the farmer seldom, in this country, weighs his cattle either dead or alive, and the butcher seldom weighs his both alive and dead. Furthermore, with an over-fat beast, though the yield in carcass is low, the butcher has the high yield of "apron" and "gut" fat, for which he pays nothing. It is the *waste* "gut" and other fat, and dripping that costs the nation so dear. In the course of our investigation, though *not* with the animals we were working on, we saw some rough offal from a slaughter-house being prepared for pigs. The pig-boy was trimming off the fat and *throwing it on the dung heap* (at the end of *the 3rd year of War*), because he told us that in his opinion, with which we agreed, so much fat "*upsets the sows.*" There remains the kitchen to consider. In this department the fat boiled off the pig-wash tells its own story, if the public care to learn from the eating-house keeper; as regards the private householder, it is well to remember that till the War came the dripping was often the perquisite of the cook.

We would once again urge the folly of allowing so much ignorance to prevail. But if the public desire enlightenment about economical methods of producing meat, such knowledge can only be obtained through investigators properly trained and equipped, and both man and material mean national cash expenditure. Our own inquiry was carried on as war-work; of equipment we had none, and our results were much more difficult to obtain in consequence.

BEEFLINGS OR BABY BEEF.

The work which we have carried through once again draws attention to the economic importance of bringing out quite young cattle as beef. Innumerable instances of its profitability have been published in leading agricultural organs, the practice has had the support of many of our most prominent farming authorities throughout the past fifty years, and there is hardly a district where one, at least, of the leading farmers does not demonstrate its possibilities from time to time. With sheep and pigs our agriculturists, as a rule, take full advantage of the early maturity propensities of their herds; yet in this, the fourth year of the War, the number of beef-beasts ready to make useful meat between the ages of 10 and 14 months is so few that their very exceptional appearance only makes the neglect of their production wholesale the more obvious and regrettable. **The practice of growing good beefling meat should be specially encouraged just now, for though producing much valuable food it demands no hard labour.**

It does, on the other hand, cause considerably *more trouble*, but this trouble the women war-workers of the country are particularly well-suited to undertake.

We have extracted the following figures from the records* of the Lord Wandsworth Institution.

The first two animals we deal with, Nos. 51 and 53† (in our main Report), had never been forced, nor finished in the ordinary sense of the word, and gave the following results (the average of the two) :—

Milk, 48·5 gal.	}	Yielded	{	673 lb. live-weight (including
Concentrates, 1,070·5 lb.				
Hay, 2,419 lb.				
Roots, 5,237 lb.				
Chaff, 52 lb.				92·5 lb. at birth).
				376 lb. of meat.

Age 12·25 months.

So that to get 1 lb. of carcass or meat it took 129 gal. of milk, 2·85 lb. of concentrates, 6·4 lb. of hay, and 14 lb. of roots and chaff.

The next two, Nos. 86 and 87‡, were forced at the end of their lives, so as to get them prime, with all the concentrates they would eat, and for the last six weeks they averaged 9 lb. per head a day. For them we get the following results :—

Milk, 47 gal.	}	Yielded	{	Live-weight 721 lb. (including
Concentrates, 1,649 lb.				
Hay, 3,142 lb.				
Roots, 4,209 lb.				
Chaff, 485 lb.				91 lb. at birth).
				384 lb. of meat.

Age 15 months.

It will take of milk 122 gal., of concentrates 4·3 lb., of hay 8·2 lb., of roots 11 lb., and of chaff 1·26 lb. to make 1 lb. of carcass or meat.

A further example, obtained since the main Report was written, was forced from birth till it was killed at 10·5 months old. Our object was to obtain a very prime young beefling so as to ascertain if it was possible to get marbled meat with such baby beef. We may say that this small carcass caused universal admiration among many practical men, butchers and farmers, who inspected it alive and dead.

Milk, 105 gal.	}	Yielded	{	Live-weight 672 lb. (including
Concentrates, 1,496 lb.				
Hay, 1,096 lb.				
Roots, 5,432 lb.				
Chaff, 164 lb.				weight at birth).
				374 lb. of meat.

Age 320 days.

* One of us (K. J. J. M.) with Miss McIlvray will publish these records in due course.

† See first table, p. 636.

‡ See second table, p. 636.

To make 1 lb. of meat in this case we use up of milk .28 lb., of concentrates 4 lb., of hay 3 lb. (nearly), of roots 14.5 lb., and of chaff .3 lb. (or nearly so).

This small bullock showed the following remarkable analysis:—

Bone	15.01
Cartilage	1.41
Fat	33.01
Lean	50.57

The marbling percentage amounted to 17.92 in the 7th rib and 9.37 in the 13th. Microscopic sections through the tissue showed a large quantity of intermuscular fat. Apart from the marbling, which is nevertheless adequate, the percentage of fat was as great as that found in the fattest prime bullock with 4 teeth up recorded in the main Report.

Seeing that it is common practice to take animals that *have already lived* till 30 months old and give them 1,120 lb. of concentrates, 720 lb. of hay, 720 lb. of chaff, and 15,680 lb. of roots during a period of 20 weeks fattening, during which time they will have increased, if they have done well, 280 lb. in live-weight, we think the above figures are eloquent. *It seems to us difficult to conceive that, once the significance of the figures we publish is realised, the beefling should go on being neglected in these days when economy in food-stuff for both man and beast forms a large part of the foundation of our future national existence.*

That it is ignorance which prevents the beefling from being more generally produced is self-evident to anyone who has seriously studied the problem of beef production; an ignorance born of prejudice forced upon the cattle husbandmen during the last half-century, when he had to banish all thoughts of high production and seek a profit where and how he could.

We wish to express our obligations to all those who have helped us in carrying out the inquiry. To the Trustees of the Lord Wandsworth Institution we are indebted for placing at our disposal the joints from 12 beeflings. We wish to thank Messrs. Vickers, Mr. Hudson, and Mr. Glasspool for their kind help in enabling us to carry out the cooking and edibility trials. We are under obligations to Messrs. Warrington, of Cambridge, for the numerous facilities with which they provided us. We are indebted to Mr. A. J. Codling for the great care and labour which he bestowed upon analysing the meat. We have to thank Mr. J. Fleming, Assistant to the Reader in Agriculture, and Mr. A. J. Burgess, the Farm Steward, for their

valued help upon that part of the work which was done upon the University Farm. Many cattle-salesmen, farmers, butchers and dealers were most helpful to us when selecting the beasts by giving us the benefit of their opinion in regard to the weights and yields of the various animals. To all who assisted in this way we wish to express our thanks.

CONCLUSION.

(1) Our examinations and observations have shown that the existing knowledge of how to estimate carcass percentage in *any one live animal* is in a chaotic state and demands much further investigation.

(2) Out of this chaos there arises from our work one observation of very considerable importance. It has been held (as exemplified by Lawes' Tables) that certain degrees of fatness indicate certain proportions of carcass weight. When this rule is applied to individual animals it results in a person whose hand touches the animal putting a far too high value upon any feeling of fatness.

(3) This leads in practice at the present moment to far too many beasts being left unslaughtered until the most economic time for killing is passed and the beasts' usefulness has diminished.

(4) In view of the practice adopted at present in estimating cattle we can recommend that all young beasts judged to be fresh stores to moderately fat may, with advantage, be slaughtered to provide meat for the nation.

(5) Aged animals (showing 4 teeth) left till they are what is known as "prime" are likely to grow fat at an inordinate expense of meat.

(6) In growing beeflings or baby-beef, there is a great potential reserve of meat in this country.

THE OFFICIAL SEED TESTING STATION AT THE FOOD PRODUCTION DEPARTMENT OF THE BOARD.

FIRST ANNUAL REPORT.

The Seed Testing Station was opened by the President on 14th November, 1917. The seed testing year 1917-1918 ended on 31st July last, as it has been decided that the testing year shall date from 1st August to 31st July. During the season now ended (8½ months) 7,744 samples were received at the station; of these 5,676 were sent by 492 seedsmen, 1,553 by 772 farmers, landowners and allotment holders, 515 samples having been tested for the Board and other Public Departments.

The number of samples of the several species tested has been as follows :—

Wheat	206	Sunflower	6
Barley	348	Maize	24
Oats	1,370	Perennial Rye-grass ..	347
Rye	10	Italian Rye-grass ..	340
Peas	93	Cocksfoot	157
Beans	61	Timothy	151
Vetches	77	Meadow Fescue	77
Turnips	323	Crested Dog's Tail ..	56
Swedes	369	Other grasses	9
Rape	75	Yarrow	5
Kale	73	Chicory	7
Cabbage	108	Red Clover	1,249
Kohl rabi	9	Alsike (including mix-	
Mustard	20	tures of Alsike and	
Broccoli	15	White Clover)	392
Mangolds	594	White Clover	313
Beet	52	Trefoil	294
Parsnips	24	Lucerne	78
Onions	145	Sainfoin	66
Carrots	44	Crimson Clover	38
Other vegetables ..	12	Other leguminous her-	
Linseed	92	bage plants	6
Hemp	1	Grass and clover mix-	
Buckwheat	3	tures	5

The distribution of samples through the seed-testing year is shown in the diagram on p. 643. It will be noted that the greatest pressure of work at the Station was from the end of December until the middle of March, the maximum number of samples (528) being received during the week ending 23rd February. The period in which the fewest samples were

received was from the middle of April until towards the end of July. The daily average of samples all through the season was 35.

That the seed trade have evinced considerable interest in the Station is shown by the fact that upwards of 70 representatives of the leading firms have visited it during the season.

A Preliminary Report on the quality of the seeds tested by 4th February last (2,400 samples) was published in the February number (Vol. 24, No. 11.) of this *Journal*; it is now proposed to give a detailed review of the results obtained on the total number of samples tested during the season. It is of interest to note that the present account deals with a far larger number of samples than have hitherto been reported upon in England and Wales. Biffen* in 1916, however, reported upon 676 samples collected by the Board during 1912, 1913 and 1914; Stapledon* reported in 1914 and 1916 on 1,239 samples collected in Central and South Wales during 1913, 1914, 1915 and 1916; Jenkin* reported upon 420 samples collected in North Wales during the period 1913-1915. A considerable amount of information is, therefore, available as to the quality of seeds put on the market during the last six years, and it is possible in certain cases to draw comparisons between the seeds used for the production of current crops and those sown during the immediately preceding years.

It will be convenient to give the chief results in tabular form for reference, and to give further particulars as to the several species separately. A summary of the main conclusions to be drawn is made at the end of the Report (p. 665.)

CEREALS.

(See Table I., p. 644.)

Wheat.—The Station opened too late in the season to deal with a representative number of samples of Autumn wheat. The average germination of all the wheat samples was 85.4 per cent., whilst that of the Spring wheats was 84.4 per cent. That the germination of the Spring wheats was less dependable

* See (a) Biffen, Professor R. H., M.A., F.R.S. Report on an Inquiry into the Quality of Farm Seeds, 1912-1914. This *Journal* Vol. XXII. February, 1916.

(b) Stapledon, R. G., M.A. Report on Seeds purchased in Central and South Wales. Seasons 1915-16. This *Journal*, Vol. XXIII. December, 1916.

(c) Report on the Condition of the Seed Trade in the Aberystwyth College Area. University College of Wales, Aberystwyth, Bulletin.

(d) Jenkin, T. J., B.Sc. Report on Seeds tested 1913-15. University College of North Wales, Bangor, Bulletin.

When these Reports are referred to in the body of the Report the name of the recorder only, e.g., Biffen, Stapledon, or Jenkin, as the case may be, is given.

Chart showing Weekly Totals from the Middle of November to the End of July.
Maximum = 528. Average = 209. Minimum = 10.

than that of the Autumn varieties is, however, shown by the fact that 28·5 per cent. of the former samples germinated under 80 per cent., whilst not more than 20 per cent. of the Autumn varieties failed to reach a germination of 80 per cent. It is to be noted that the average germination of wheat was considerably less than that of barley or oats, and that the number of samples received with a germination of less than 80 per cent. was also greatest in the case of wheat, practically 6 per cent. of the samples actually germinating less than 50 per cent. Many of the poorest samples were sent by farmers who asked whether their grain was fit for sowing, so that it is reasonable to suppose that the adverse reports sent out by the Station on such samples prevented the bulks they represented being used for that purpose. Four per cent. of the samples were contaminated with "bunt" (*Tilletia tritici*). Two samples contained Ear Cockle (due to the eelworm *Tylenchus scandens*) and a large number of the poorer samples were badly sprouted. Several instances of the depressing influence of some of the proprietary seed dressings on germination were noted.

TABLE I.—*Showing the Percentage Germination of Cereals and Pulses.*

		Highest Per- centage.	Lowest Per- centage.	Average Per- centage.	Percentage of Samples Germinating between			
					100-90 Per cent.	89-80 Per cent.	79-51 Per cent.	50-0 Per cent.
Wheat	..	100	10	85·4	65·6	10·9	17·6	5·9
Barley	..	100	16	89·4	71·0	13·8	12·5	2·7
Oats	..	100	20	89·5	65·3	25·7	8·1	·9
Rye	..	96	58	84·8	50·0	30·0	20·0	—
Peas	..	100	35	86·7	61·2	21·1	15·5	2·2
Beans	..	100	0	88·4	67·4	16·3	11·4	4·9
Vetches	..	99	4	77·6	40·9	25·0	21·0	13·1

Barley.*—The average germination of barley was practically the same as that of oats, but a larger number of high class samples of barley was received than of either oats or wheat. Most of the barley sent from the Midland and Eastern Counties was excellent; the germination of samples from Hants. Devon, Cornwall, and most of the Welsh counties was, however, decidedly poor, the great majority of samples with germinations of less than 75 per cent. coming from these districts. About 10 per cent. of the samples were badly contaminated with the spores of the "closed" smut (*Ustilago Hordei*) and a considerable number were badly sprouted.

* A portion of most of the barley samples has been sent to Mr. E. S. Salmon, of the South Eastern Agricultural College, Wye, for investigation in reference to "Smut" in barley.

Oats.—Since over 1,300 oat samples were tested, a sufficient number has been received for the averages from certain groups of counties to be compared. For this purposes only samples stated "as grown" in the various counties have been considered. The figures in brackets represent the number of samples averaged in each case. The averages are as follows:—

Germination.			Germination.		
Per cent.			Per cent.		
Scotland	(74)	94.4	Somerset, Wilts and		
Isle of Man	(64)	91.8	Dorset	(15)	89.0
Northern Counties	(20)	91.5	Wales	(90)	88.6
Ireland	(29)	91.6	Devon and Cornwall	(110)	86.5
Midlands	(50)	90.2	Kent, Surrey, Sussex and Hants	(40)	83.0

It is interesting to note that the southern and western counties gave the poorest germinations, and that these counties and Wales contributed the greatest number of samples with germination below 80 per cent. The Scotch oats not only gave the best average, but only 1.3 per cent. of these germinated less than 90 per cent. The average germination of black oats was one per cent. lower than that of other oats. A considerable number of samples, especially from Wales, Devon, Cornwall and some of the southern counties, showed evidence of having been heated in the stack, whilst an appreciable number were sprouted. A number of the oat samples contained varying proportions of shelled grain, and it was found that on an average the germination of shelled grain was 26 per cent. lower than that of the normal unshelled grain constituting the sample. It was also found that the shelled grain did not in many cases germinate normally.*

Rye.—The number of samples of rye tested was not sufficient for the results to be taken as representative, but, as might have been expected, the average germination proved to be lower than that of other cereals. One sample contained several ergots (*Claviceps purpurea*).

Purity in Cereals. Several samples containing upwards of 1.5 per cent. of weed seeds were received. One sample of wheat contained 10 per cent. of weeds, mostly corncockle (*Lychnis Githago*), a sample of oats 8 per cent. of wild radish (*Raphanus Raphanistrum*), a sample of rye 1.8 per cent. of soft brome grass (*Bromus mollis* et spp.), and a sample of barley nearly 3 per cent. of knapweed (*Centaurea nigra*): it was, however, the exception for cereals to contain a high

*Further investigations are in progress, and this and other data collected in connection with the large number of oats tested will be reported upon subsequently.

percentage of impurity. The samples sent to the Station by farmers none the less indicate that enough attention is not paid to the purity of cereals for sowing. It should be realised that even $\frac{1}{2}$ per cent. of weed seeds in cereals, sown as they are in terms of bushels to the acre, is sufficient to introduce a large number of weeds like charlock (*Brassica Sinapis*), docks (*Rumex* spp.), black bindweed (*Polygonum Convolvulus*), and soft brome (*Bromus mollis et* spp.) on to the land.*

The most commonly occurring weed seeds in cereals were in approximate order of their frequency as follows:—

Black Bindweed (<i>Polygonum Convolvulus</i>).	Creeping Thistle (<i>Cirsium arvense</i>).
Charlock and Wild Turnip (<i>Brassica</i> spp.).	Knot-grass (<i>Polygonum aviculare</i>).
Cleavers (<i>Galium Aparine</i>).	Wild Oat (<i>Avena fatua</i>).
Wild Radish (<i>Raphanus Raphanistrum</i>).	Hemp Nettle (<i>Galeopsis tetrahit</i>).
Redshank (<i>Polygonum Persicaria et lapathifolium</i>).	Field Foxtail (<i>Alopecurus myosuroides</i>).
Fat Hen (<i>Chenopodium et Atriplex</i> spp.).	Darnel (<i>Lolium temulentum</i>) (chiefly in rye).
Dock (<i>Rumex</i> spp.).	Venus' Comb (<i>Scandix pecten</i>).
Wild Vetches (<i>Vicia</i> spp.).	Fool's Parsley (<i>Aethusa cynapium</i>).
Knapweed (<i>Centaurea nigra</i>).	Poppy (<i>Papaver</i> spp.).
Campions (<i>Lychnis et Silene</i> spp.).	Field Alkanet (<i>Lycopsis arvensis</i>).
Bindweed (<i>Convolvulus arvensis</i>).	Sun Spurge (<i>Euphorbia helioscopia</i>).
Corn Cockle (<i>Lychnis Githago</i>).	
Soft Brome (<i>Bromus mollis et</i> spp.).	

The wheat and barley samples frequently contained appreciable amounts of broken seed, whilst wheat often contained much barley and some oats; barley and oats were moreover very general impurities in each other.

PULSES AND TARES.

(See Table I., p. 644.)

Peas.—The average germination of garden peas was 86 per cent., the highest germination being 100 per cent., and the lowest 35 per cent. The average for the 15 samples of field peas received was 87 per cent., with a highest germination of 100 per cent. and lowest of 42 per cent., whilst 17 per cent. of all the pea samples germinated under 80 per cent. Several of the field pea samples were badly sprouted, whilst a large

* See "The Quality of Agricultural Seeds," this *Journal*, Vol. XXIV., February, 1918, p. 1203.—"Purity in Cereals."

number of the garden samples consisted of old seed. Practically all the garden samples were pure except for small amounts of broken seed. Some of the field samples contained as much as 10 per cent. of broken seed; one of these samples contained a considerable amount of wild oat (*Avena fatua*), whilst the seeds of cereals were also common impurities in the field peas. Three per cent. of the pea samples were attacked by beetles (*Bruchus* spp.).

Beans.—The average germination and the range of germination (in brackets) for the various classes of beans tested was as follows :—

Field beans	97.1	per cent.	(100–80).
Broad beans	93.4	„	(100–48).
Scarlet runner beans	80.1	„	(98–48).
Dwarf French beans	62.7	„	(86– 0).

The number of samples tested was not sufficient for the above figures to be taken as representative, but it is evident that scarlet runners and French beans in particular were of poor average quality. The bean samples were free from weed seeds, but frequently contained from .5 per cent. to 2 per cent. of broken seeds, and about 7 per cent. of the samples were attacked by beetles (*Bruchus* spp.).

Tares or Vetches. The quality of the vetch samples was decidedly poor, giving an average germination of only 77.6 per cent. with 13 per cent. of the samples germinating below 51 per cent.; several of the poorest samples were badly sprouted. The purity of vetch samples was also low, the average impurity amounting to 4.48 per cent. independent of rye, which frequently contributed over 10 per cent. to the samples. The chief impurity was broken seed, which, in some instances, amounted to 10 per cent. and in one case to as much as 17 per cent. The chief weed seeds present were :—

Cleavers (*Galium Aparine*) (in 32 per cent. of the samples), corn cockle (*Lychnis Githago*) (in 10 per cent. of the samples), daniel (*Lolium temulentum*), black bindweed (*Polygonum Convolvulus*), poppy (*Papaver* spp.), bindweed (*Convolvulus arvensis*), cornflower (*Centaurea Cyanus*), and corn crowfoot (*Ranunculus arvensis*). A few samples were attacked by beetles (*Bruchus* spp.).

ROOTS: CERTAIN FORAGE CROPS: CERTAIN VEGETABLES AND LINSEED.

(See Table II., p. 648.)

Mangolds.—The mangold seeds on the market were probably above the average of recent years, the average germination*

* The germinations of mangold and beet are expressed in terms of the number of seedlings developed per 100 seed clusters.

being 137.8 per cent. compared with 116.4 per cent. and 116.7 per cent. given by Biffen for 1912 and 1914 respectively.

A large number of poor samples with germination below 100 per cent. were, however, received at the Station.

In the main, as far as can be gathered from germination trials, the seeds were very true to type, and Biffen found the same to apply to the samples tested in 1912 and 1914. It is of interest to note that the majority of the mangold seeds were at least yearlings, thus showing that the seeds of this plant may improve rather than deteriorate by being kept for a year.

TABLE II.—*Showing the Percentage Germination of Root and Vegetable Crops.*

	Highest Per-centage.	Lowest Per-centage.	Average Per-centage.	Percentage of Samples Germinating between			
				100-90 Per cent.	89-80 Per cent.	79-51 Per cent.	50-0 Per cent.
Turnip ..	100	1	83.7	41.6	34.0	21.3	3.1
Swede ..	100	0	79.9	37.6	30.3	25.4	6.7
Rape ..	99	52	90.2	67.7	28.1	4.2	—
Kale ..	99	12	71.5	27.9	14.7	30.1	21.3
Cabbage ..	96	2	73.5	16.8	29.2	42.6	11.2
Parsnip ..	84	0	45.0	—	10.0	45.0	45.0
Onion ..	100	1	78.9	40.8	24.2	27.5	7.5
Carrot ..	94	6	62.8	2.3	43.3	57.1	23.3
Linseed ..	100	29	87.2	66.2	12.0	16.4	5.4
				Over 200 Per cent.	100-150 Per cent.	149-100 Per cent.	99 Per cent.
Mangold ..	268	0	137.8	5.6	36.2	42.6	15.6
Garden Beet ..	191	10	84.0	—	13.0	13.0	74.0
Sugar Beet ..	226	14	143.8	17.3	30.5	39.2	13.0

Sugar Beet. Only a few samples were tested; these gave the satisfactory average germination of 143.8 per cent.

Turnip and Swede.—It is to be noted that the average germination of the turnip samples was decidedly higher than that of the swedes, but since the average figure for both was less than 85 per cent. the quality of these seeds was probably below the average of normal years. Over 20 per cent. of the samples of both germinated less than 80 per cent., eight samples being received with germinations of less than 10 per cent.

Several of the poorer samples of these and other crucifers were more or less badly sprouted.

Rape. The average figure for rape (90.2 per cent.) was over 6 per cent. better than that of any of the other crucifers, and this, together with the fact that only 4 per cent. of the samples germinated below 80 per cent. and none under 50 per cent., suggests that the average quality of this seed was good.

Kale.—The majority of the kale samples were decidedly poor, 21 per cent. germinating less than 51 per cent., and the average being only 71·5 per cent.

Cabbage.—The average germination of the garden varieties of cabbage, including savoy, was 75 per cent., and the average germination of field cabbages 72 per cent. The quality of the cabbage samples was thus appreciably below that of the turnip and swede and a little better than the kale.

Parsnip.—Parsnip seed seldom reaches a high percentage of germination; the average figure, 45 per cent., was, however, lower than that reported by Jenkin (on comparatively few samples) in 1915. This seed undoubtedly needs to be purchased with great caution, for 4 out of the 21 samples received failed to germinate; 1 only reached 2 per cent. and another only 14 per cent.

Onion.—The average germination of the onion samples (78·9 per cent.) was decidedly satisfactory, as also the fact that only about 7 per cent. of the samples received failed to germinate over 50 per cent. This compares favourably with the figures obtained for other vegetables. It must be pointed out, however, that the great majority of the samples tested were of Californian origin, a large proportion of which attained to a germination of over 90 per cent., 54 per cent. being the lowest figure recorded. Three French samples gave an average germination of 65 per cent.; whilst four English grown samples gave an average germination of only 57 per cent.

Carrot.—The average germination of the carrot samples was below 65 per cent., 94 per cent. being the highest figure recorded, whilst practically a quarter of the samples failed to germinate over 50 per cent. A large proportion of the samples could not, therefore, have been relied upon to give a satisfactory plant.

Garden Beet.—100 per cent. may be regarded as a satisfactory germination for garden beet; 74 per cent. of the samples received, however, failed to reach this figure, the average germination being only 84 per cent., which indicates a poor quality of seed.

Purity in Roots and Vegetables.—The seeds of roots and vegetables are usually, but by no means always, sent out in a high state of purity. Turnip, swede, cabbage and other crucifers frequently contain appreciable amounts of broken seed, 2 per cent. being not uncommon. Mangold, beet, onion, parsnip and carrot samples often contain a considerable amount of stem and chaffy matter with soil or dirt. As much as 10 and even 20 per cent. of inert matter has been met with in onion and mangold samples.

Weeds are not totally absent from root samples; and 2 per cent. of weeds have been found in some cases. The chief weed seeds occurring in roots and vegetables are:—

Campions (*Silene et Lychnis* spp.), black bindweed (*Polygonum Convolvulus*), nipplewort (*Lapsana communis*), buttercup (*Ranunculus* spp.), docks (*Rumex* spp.), cleavers (*Galium Aparine*), and chickweed (*Stellaria et Cerastium* spp.), with black mustard (*Brassica nigra*) in turnip, swede, and other crucifers.

Linseed.—The great majority of the linseed samples tested were from seed harvested in England. Although many of the samples had been selected, the average figure of 87·2 per cent. and the fact that 66 per cent. of the samples germinated over 90 per cent. indicate that seed with a satisfactory germinating capacity can be harvested in this country. The following average figures for linseed harvested in certain groups of counties, although not based on a sufficiently large number of samples, are of interest:—

4 samples	ex Northumberland, Cumberland, and Westmorland.	Average Germination	94 per cent.
49	„ Cambs, Norfolk, Essex, Herts, and Suffolk	93 „
4	„ Surrey and Sussex	92 „
8	„ Devon and Somerset	80 „

Two samples of linseed (from Essex) contained seeds of the Linseed Dodder. The chief impurities met with in samples (many of which had not been cleaned) were as follows:—

Fat hen (*Chenopodium* spp.), dock (*Rumex* spp.), redshank (*Polygonum Persicaria*), knot-grass (*Polygonum aviculare*), bindweed (*Convolvulus arvensis*), orache (*Atriplex* spp.) and excess of charlock (*Brassica sinapis*) and other crucifers.

GRASSES.

(See Table III., p. 651, and Table IV., p. 652.)

Perennial Rye-grass.—The average germination of 77·1 per cent. was somewhat below the average figures recorded by Stapledon and Jenkin for 1915 and 1916, but higher than the figures given by Biffen for 1912 and 1913. The majority of the samples germinated between 80 per cent. and 90 per cent. The Irish and English samples gave a very similar average germination, whilst the samples from Scotland were somewhat higher. The average purity (*i.e.*, 2·23 per cent.) cannot be regarded as satisfactory when it is realised that 51 per cent. of the samples contained 1 per cent. or over of injurious weed seeds. These consisted for the most part of Yorkshire fog (*Holcus lanatus*) and soft brome (*Bromus mollis*), both of which occurred in varying amount in over 90 per cent. of the samples, as much as 10 per cent. of these weeds having been

met with in samples. Rat's tail fescue (*Festuca bromoides*), suckling clover (*Trifolium dubium*), cat's ear (*Hypchoeris radicata*) and buttercup (*Ranunculus* spp.) were also frequently occurring weed seeds in perennial rye-grass.

TABLE III.—Showing the Percentage Purity and Germination of Grasses.

	Average percentage of Impurities.	Percentage of Samples with 1 per cent. or over of Injurious Weeds.	Percentage of Germination.			Percentage of Samples Germinating between			
			Highest.	Lowest.	Average.	100-90 Per cent.	89-80 Per cent.	79-51 Per cent.	50-0 Per cent.
Perennial Rye-grass	2.23	51.0	98	14	77.1	13.4	42.0	39.1	5.5
Italian Rye grass	1.19	33.0	98	34	75.7	8.3	30.0	59.7	2.0
Cocksfoot..	6.64	6.0	95	1	62.7	3.2	15.6	57.6	23.6
Timothy ..	1.74	1.0	100	0	85.3	64.7	12.9	16.3	6.1
Meadow Fescue	3.28	23.0	99	12	57.3	10.5	17.1	28.9	43.5
Crested Dog's Tail	2.05	6.0	93	2	66.2	7.4	29.6	42.7	20.3

Italian Rye-grass.—The average germination was a little lower than that of perennial rye-grass, a much larger number of these samples germinating below 80 per cent.

The average was higher than that recorded by Biffen for 1913, but lower than Biffen's figure for 1912 or Stapledon's and Jenkin's figures for 1915 and 1916.

The samples from Scotland gave a higher average germination than those harvested in Ireland, France, or England. Perennial rye-grass frequently occurred in large amount in samples of Italian rye-grass. The average purity (independent of included perennial rye-grass) was higher than that of perennial rye-grass. Injurious weeds were on the average less abundantly present, Yorkshire fog (*Holcus lanatus*) and cat's ear (*Hypchoeris radicata*) in particular being less frequent. It will be noted, however, that in the main the distribution of weed seeds in the two rye-grasses was very similar and differed in several respects from that in other grasses.

Ergot (*Claviceps purpurea*) was present in a few samples; and several samples would seem to have represented bulks that had been carried over from a previous year and badly stored, in so much as they showed evidence of having been attacked by mice and (or) insects.

Cocksfoot.—The average germination of 62.7 per cent. was lower than the various figures recorded by Biffen, Stapledon and Jenkin for the previous five years; over 20 per cent. of

TABLE IV.—Showing the Percentage Occurrence of Certain Weed and other Seeds in Samples of Grasses.

	Perennial Rye-grass.	Italian Rye-grass.	Cocksfoot.	Meadow Fescue.	Crested Dog's Tail.
Buttercup (<i>Ranunculus</i> spp.)	28	17	26	1	6
Trefoil (<i>Medicago lupulina</i>)	3	10	27	5	4

Yorkshire Fog (<i>Holcus lanatus</i>)	97	77	56 81	11 18	60 28
Rye-grass (<i>Lolium</i> spp.)	—	—	—	—	—

The following percentage occurrences were also found:—

Anthemis arvensis—14 in Cocksfoot. *Plantago aristata*—33 in Meadow Fescue. *Polygonum Persicaria* et spp.—18 in Meadow Fescue. Dock (*Rumex* spp.)—23 in Meadow Fescue, 2 in Crested Dog's Tail. Nipplewort (*Lapsana communis*)—56 in Crested Dog's Tail. *Aira Caryophylla*—20 in Crested Dog's Tail.

the samples under review moreover germinated less than 51 per cent. The average of four American samples gave a germination of 79.2 per cent., the average of the Danish samples was 75.0 per cent., whilst that of seven French samples was 62.1 per cent. It will be noted that the average impurity of cocksfoot was as high as 6.64 per cent., being considerably higher than that of other grasses. The most abundant impurity in cocksfoot was, however, perennial rye-grass, which not infrequently constituted over 10 per cent. of the sample. Other useful grasses often occurring in cocksfoot to an appreciable extent were meadow fescue, sweet vernal grass and tall oat grass. Yorkshire fog (*Holcus lanatus*) and soft brome (*Bromus mollis*), however, both occurred in over 50 per cent. of the samples, and not infrequently to an extent of over 1 per cent. It is interesting to note that trefoil occurred more frequently in cocksfoot than in other grasses, whilst *Anthemis arvensis* was not uncommon in samples of cocksfoot.

Timothy.—Timothy invariably attains to a higher average germination than other grasses; and a germination of well over 90 per cent. should always be expected. This fact, together with the large number of seeds to the pound, entitles Timothy to be considered as one of the cheapest grass seeds. It is evident, however, that the average quality of Timothy samples (germination 85.3 per cent.) has been relatively poor this year.

Biffen recorded an average real value of 92.6 per cent. in 1913, and Stapledon recorded an average germination of 95 per cent. in 1913 and 94 per cent. in 1916; Jenkin, however, reporting on a few samples in 1915, gives an average of 81 per cent. That very poor (generally old) samples of timothy are put on the market is, however, indicated by the fact that one sample was received incapable of germination and that 6 per cent. of the samples germinated less than 51 per cent.

Timothy samples frequently contained less than .5 per cent. of impurity, and when impure the most frequent and abundant impurities were the seeds of alsike and white clover (both occurring in over 50 per cent. of the samples) and weed seeds (see Table VI., p. 656) such as are most usually met with in small clovers, *e.g.*, sheep sorrel (*Rumex Acetosella*), which was found in 44 per cent. of the samples.

That timothy does not usually contain a large amount of injurious weed seeds is shown by the fact that only 1 per cent. of the samples included 1 per cent. or over of such weeds.

The nature of the impurities in Timothy, moreover, indicated that the great majority of the samples were of North American origin; *Potentilla monspeliensis*, for instance, was found in 41 per cent. of the samples. It should be noted that dodder (*Cuscuta* spp.) was found in a few of the samples tested.*

Meadow Fescue.—The average germination of meadow fescue (57.3 per cent.) was lower than that of any of the other grasses and also lower than that of any of the leguminous herbage plants, with the single exception of sainfoin.

That meadow fescue was much below the average quality of recent years is suggested by the fact that 80 per cent. (in 1913) is the lowest average given in the records (1913–16) previously referred to. A limited number of high class samples were, however, obtainable, for despite the low average germination 10 per cent. of the samples germinated over 90 per cent.

Soft brome (*Bromus mollis* et spp.) was the most frequently occurring injurious weed seed in meadow fescue, 23 per cent. of the samples containing 1 per cent. or over of injurious weed seeds (almost wholly varieties of soft brome). *Plantago aristata*, although not harmful as a weed in this country, is a common impurity in meadow fescue, and the seeds of dock (*Rumex* spp.) were more frequently met with than in samples

* Stapledon, in 1916, recorded the presence of clover dodder in two out of 28 samples of Timothy.

of other grasses. Several of the samples contained high percentages of perennial rye-grass; 16 per cent. and 32 per cent. of this valuable, but much cheaper seed being met with, and one sample sent to the Station as meadow fescue contained 36.5 per cent. of cocksfoot. There is little doubt that a large number of the samples sent to the Station represented old stocks, for the seed of this grass does not keep well.

Crested Dog's Tail.—The average germination of this grass was 66.2 per cent., and it is interesting to note that the average germination of ten samples stated to have been grown in Ireland was 74.8 per cent. Four samples were received with a germination of less than 7 per cent. Crested dog's tail samples frequently contained over 1 per cent. of weed seeds; the "injurious" weeds being most usually Yorkshire fog (*Holcus lanatus*) caryopses, sheep sorrel (*Rumex Acetosella*) and suckling clover (*Trifolium dubium*) (not now scheduled with injurious weeds). Nipplewort (*Lapsana communis*), crepis (*Crepis virens*), prickly sowthistle (*Sonchus asper*), cat's ear (*Hypochoeris radicata*), madder (*Sherardia arvensis*) and ox-eye daisy (*Chrysanthemum leucanthemum*) were moreover characteristic impurities in this grass. Crepis (*Crepis virens*) should certainly be regarded as a harmful weed, for it frequently abounds in young leys treated as meadows; whilst ox-eye daisy (*Chrysanthemum leucanthemum*) rapidly reproduces itself when introduced into prepared meadows. Rye-grass and Timothy with such small grasses as *Poa* spp., *Agrostis* spp., silver hair grass (*Aira caryophyllea*) and *Alopecurus geniculatus* were also commonly met with in samples of crested dog's tail.

CLOVERS AND OTHER LEGUMINOUS HERBS.

(See Table V., p. 655, and Table VI., p. 656.)

Red Clover.—No distinction has been made between "broad red clover," "late flowering red clover," and ordinary "cow grass" in this Report. It will be noted that the average germination of the large number of red clover samples received (1,249) was only 67 per cent.; which is about on a par with the figures given by Biffen for 1912, 1913 and 1914, but decidedly lower than the figures given by Stapledon for 1916. The average impurity, although over 3 per cent., was less than that of alsike or white clover. Attention is directed to the particulars given in Tables VI. and VII. relative to the country of origin of red clovers. It will be noted that the germination of Chilian and Canadian samples was nearly the same, the average figure for both being practically 90 per cent., none of the

samples germinating less than 50 per cent. The French samples also reached the high average figure of 87·2 per cent., with not more than 5 per cent. of the samples germinating less than 50 per cent. The British samples, however, only averaged just over 60 per cent.,* with nearly 30 per cent. germinating under 50 per cent., of which a large proportion failed to reach 10 per cent.; a considerable proportion of the British samples were, of course, representative of "yearling" or "over-year" stocks.

TABLE V.—*Showing the Percentage Purity and Germination of Clovers.*

Crimson Clover	2·14	Nil.	99	7	81·4	·1	51·5	12·2	30·3	6·0

* Two samples contained over 5 per cent. of Burnet.

The fact that the Chilian and Canadian samples contained on the average nearly twice as much "hard" seed as the British and French is also of interest as indicating that "hardness" in red clover seed is influenced to a marked degree by climatic conditions, and that those climatic factors which make for excellence of germination also tend to favour hardness.†

In the matter of purity also the British samples will be seen on the average to have been more impure than the imported samples, whilst those from Chili and Canada were of the highest average purity.

The facts given in Table VI. as to the specific weed seeds of commonest occurrence in red clovers of different origin are of considerable interest and may be briefly summarised as follows:—

* The average figure given by Stapledon for British red clovers tested in 1916 was over 80 per cent.

† It has been noted also that samples harvested in Wales and the West of England tend to be less "hard" than those saved in our eastern and southern counties.

* Mainly Spear Thistle in Chilian Red Clover and Creeping Thistle in the other cases.

The following percentage occurrences were also found:—

Camelina microcarpa—14 in Alsike, 5 in Timothy. *Lepidium* spp.—3 in Alsike, 16 in Timothy. *Sisymbrium altissimum*—1 in Canadian Red Clover, 5 in Alsike, 1 in Timothy. *Potentilla monspeliensis* et spp.—4 in Alsike, 41 in Timothy. *Centaurea maculosa*—16 in Lucerne. *Rudbeckia hirta*—9 in Timothy. *Plantago Rugelii*—1 in Canadian Red Clover, 1 in Alsike, 8 in Timothy.

CHILIAN.—These samples contained the seeds of Chilian clover dodder in no less than 82 per cent. of the samples, over 1 per cent. of this parasite being six times met with and one sample containing as much as 5.2 per cent. Of harmful weeds to grass land in this country these samples contained both docks (*Rumex* spp.) and thistles (*Cirsium* spp.) more frequently than clovers from other sources. The cranesbills (*Geranium* spp.), wild carrot (*Daucus carota*) and champions (*Silene* et *Lychnis* spp.) were, however, not frequent in Chilian samples; diagnostic features were the occurrence of lucerne (also abundant in French samples) and in particular the presence of seeds of various species of *Brassica* and of *Melilotus*.

TABLE VII.—*Showing Comparative Purity and Germination of Red Clovers of Different Nationalities.*

	Average per-centage of Im-purities.	Percentage of Germination.			Average per-centage of Hard Seed.	Percentage of Samples Germinating between			
		Highest.	Lowest.	Average.		100-90 Per cent.	89-80 Per cent.	79-51 Per cent.	50-0 Per cent.

Canadian ..	1.41	97	66	88.9	6.9	60.8	32.1	7.1	Nil

Five samples out of 1,250 contained 1 per cent. or over of Injurious Weeds.

No figures are given for Clovers from U.S.A. since it appeared that many of the samples sent in as "American" were either of Canadian or Chilian origin.

CANADIAN.—These clovers have been regarded as being remarkably free from dodder; this parasite (usually the Chilian species) was, however, found in 30 per cent. of the samples sent to the Station as Canadian. Of harmful weed seeds, sheep sorrel (*Rumex Acetosella*) was more frequent in Canadian than other samples; dock (*Rumex* spp.) was also frequent, andampions (*Silene* et *Lychnis* spp.) were not uncommonly met with. Wild carrot (*Daucus carota*) and cut-leaved geranium (*Geranium dissectum*), although much less plentiful than in British samples, also occurred. Diagnostic features were the frequent occurrence of fat hen (*Chenopodium* spp.), *Polygonum* spp., *Setaria viridis*, and *Ambrosia artemisiifolia*. Timothy and alsike clover also occurred in half the samples. It may be remarked that rib-grass (*Plantago lanceolata*), which is the outstanding impurity in red clovers generally, occurred less frequently in Canadian than other samples.

FRENCH.—The weed seeds met with in these samples were in the main very similar to the British. The most striking feature of the French clovers was, however, the frequent presence of wild carrot (*Daucus carota*), which occurred considerably more often in French than in British samples, the position, however, being reversed in the case of cut-leaved cranesbill (*Geranium dissectum*). Bird's-foot trefoil (*Lotus corniculatus*), ox-tongue (*Picris echioides*) and *Verbena* spp. are in the main to be regarded as characteristic French impurities. Lucerne and chicory also occurred more often in French than in other samples. The European clover dodder was frequent in both French and British samples.

BRITISH.—Rye-grass, trefoil and knotted parsley (*Caucalis nodosa*) were impurities more essentially met with in British and French samples, whilst cut-leaved cranesbill (*Geranium dissectum*) is to be regarded as the most characteristic British weed. Campions (*Silene* et *Lychnis* spp.), madder (*Sherardia arvensis*) and soft cranesbills (*Geranium molle* et *pusillum*) were also more plentiful in British than in other samples, whilst docks (*Rumex* spp.), more plentiful than in French samples, occurred to a greater extent in both Chilian and Canadian clovers.

A large number of samples sent to the Station as British almost certainly contained at least an admixture of red clover of other nationalities, containing as they did weeds such as *Setaria viridis*, *Verbena* spp., *Amaranthus* spp., *Ambrosia* spp., *Malva* spp. and *Melilotus* spp., and other foreign impurities. Moreover, Chilian dodder was found in over 30 samples purporting to be of British origin.*

The significance of the above facts as to the nationality of red clovers is referred to in the summary at the end of the Report.

About a dozen samples were sent to the Station described as "ribby" red clover; these were mixtures of ribgrass and red clover in about equal proportions, and were remarkable for the fact that their average purity was less than that of red clovers proper.

The majority of the red clovers received were not accompanied with a statement as to their nationality. Many of these were designated "yearling;" 70 of such samples gave an average germination of but 16.4 per cent.

The balance of samples consisted chiefly of blends of different nationalities, and the evidence suggested that several of these were so made up that the contained British seed did not contribute very materially to the germination of the blend as such.

With regard to the purity of red clovers as a whole, although comparatively few samples contained 1 per cent. of injurious weed seeds as scheduled in the Order, it is to be noted that dock (*Rumex* spp.) contributed over 1 per cent. to three samples. Campions (*Silene* et *Lychnis* spp.) and cut-leaved cranesbill (*Geranium dissectum*), however, occurred to an extent of 1 per cent. and over in several samples, the former having reached 5 per cent. Ribgrass (*Plantago lanceolata*), rye-grass and trefoil have all been met with to an extent of over 10 per cent.

Alsike Clover.—The average germination of alsike clover (75.3 per cent.) was higher than that of either red or white clover, and was also higher than the average figures obtained by Biffen in 1912, 1913, or 1914, or by Stapledon in 1913, but not quite as high as Stapledon's or Jenkin's figures for 1915 and 1916.

It is of interest to note that the alsike samples were very variable, for whereas 20 per cent. of the samples germinated

* The question of the country of origin of red clovers is now under further investigation at the Station, and it is hoped to publish a Report on the work at a later date.

90 per cent. or over, 12 per cent. failed to reach 51 per cent. The average impurity of alsike clover, although greater than that of red, was considerably less than that of white clover, which is in accord with results obtained in previous years.

The most striking feature in reference to specific impurities was the comparative scarcity of dodder (*Cuscuta* spp.) which would seem to have been less plentiful in this clover since the War, as the figures in Table VIII. indicate.

TABLE VIII.

Year and Recorder ..	1912. Biffen.	1913. Biffen.	1914. Biffen.	1915. Stapledon.	1916. Stapledon.	1918. S.T.S.
Percentage number of samples in which Dodder occurred.	65	38	32	about 10	about 6	less than 1

In this connection it is to be noted that the evidence of the contained weed seeds (see Table VI.) shows that a very large proportion of the samples were of North American origin, European supplies having doubtless been cut off to a large extent as the direct result of the War.

The harmful weed seeds chiefly met with in alsike were champions (*Silene et Lychnis* spp.), soft cranesbills (*Geranium molle et pusillum*) (much more plentiful in white clover), self heal (*Prunella vulgaris*), sheep sorrel (*Rumex Acetosella*), thistle (*Cirsium* spp.), forget-me-not (*Myosotis scorpioides*), and May-weeds (*Anthemis* spp.), whilst white clover, suckling clover, trefoil and Timothy were of frequent occurrence. Injurious weeds (even when suckling clover is included amongst these) did not, however, frequently exceed 1 per cent., sheep sorrel (*Rumex Acetosella*), self heal (*Prunella vulgaris*) and soft cranesbills (*Geranium molle et pusillum*) being the more harmful weeds met with in the greatest amount.

White Clover (not including *Wild White*).—Although the average germination of white clover was not much below that of alsike, far fewer samples reached a germination of 90 per cent. or over. As in the case of alsike, dodder would seem to have been progressively less frequent over the period 1912-18. Biffen gives the average percentage occurrence for 1912, 1913 and 1914 together as 35 per cent., and Stapledon for 1915-16 together gives the figure 19 per cent. The figure for 1918 obtained on the samples under review was only just over 1 per cent.

It is interesting to note that dodder was only found in samples of white clover which also contained considerable amounts of red clover.

White clover will be seen on the average to have contained a considerably higher percentage of impurity than other clovers or grasses. It is to be noted, however, that trefoil was frequently present in large amounts, 20 per cent. of this useful but relatively much cheaper seed having been met with. Suckling clover was of equally frequent occurrence, 5 per cent. of this impurity being not uncommon, and as much as 17 per cent. having been met with. The extent to which suckling clover occurred even in ordinary white clover was moreover indicated by the fact that 17 per cent. of the samples contained 1 per cent. or over of "injurious" weed seeds, sheep sorrel (*Rumex Acetosella*) being the injurious weed proper associated with suckling clover in these cases. Sheep sorrel (*Rumex Acetosella*), however, although of very frequent occurrence in white clover, was found even more often in alsike. The outstanding weed impurities met with in white clover were soft cranesbills (*Geranium molle et pusillum*), which occurred in varying amount in 82 per cent. of the samples, as much as 4 per cent. being frequent and 12 per cent. having been more than once met with. Mouse-eared chickweeds (*Cerastium* spp.) were a fairly frequent impurity, one sample containing 18.5 per cent. of these weeds; champions (*Silene et Lychnis* spp.), madder (*Sherardia arvensis*), self heal (*Prunella vulgaris*) and forget-me-not (*Myosotis scorpioides*) were also of frequent occurrence in white clover. It is to be noted that both alsike and white clover contained considerably more "hard" seed than did red clover seed, this being in accord with the records for previous years.

Wild White Clover.—A comparison between samples of white clover and samples sent to the Station as wild white clover may be of interest.

Of the 30 samples of wild white, the majority were doubtless genuine, but in a few cases the nature of the contained weed impurities suggested that the samples were not wholly gathered from permanent pasture. The occurrence of such typical weeds of arable land and rotation grass as field madder (*Sherardia arvensis*), field forget-me-not (*Myosotis scorpioides*) and stinking mayweed (*Anthemis cotula*) in certain samples and the fact that over half the samples contained varying amounts of alsike, would appear to indicate either some admixture of ordinary white clover seed or the probability that some of the samples were wild white "once grown." This naturally raises the question as to the desirability or otherwise of describing "once grown" wild white as true wild white. In view of

the limited amount of information on this subject, and the fact that a buyer of wild white naturally expects a sample that has been harvested direct from permanent grass land, the opinion of the Station is that the term "wild white clover" should be applicable only to seed so harvested and not to seed "once grown."

TABLE IX.—Showing comparatively the Purity, Germination and Contained Impurities of White and Wild White Clovers.

		White Clover.	Wild White Clover.
Average percentage of impurity	9.98	..	16.18
Percentage of samples with 1 per cent. and over of injurious weeds	17.2	..	70.0
Percentage germination. Highest	98	..	91
" " Lowest	0	..	14
" " Average	72.3	..	64.2
Average percentage of hard seed	8.0	..	15.0

Occurrence of weed and other seeds per 100 samples.

<i>arvensis</i>)	49	7	Timothy	10	20
Mayweed (<i>Anthemis</i>			Yorkshire Fog	3	40
<i>cotula</i>)	4	3			

The above table (Table IX.) gives comparative figures for the two white clovers. The purity and germination of the wild white, as might be expected, is lower than that of ordinary white clover, whilst the amount of hard seed is higher. With respect to weed and other impurities, the fact that most of the impurities in wild white are seeds of other useful plants, mainly the grasses and leguminous plants of old pasture, must be noted. The most characteristic impurities of wild white would appear to be the seeds of woodrush and sedges (*Luzula* and *Carex* spp.), cinquefoil (*Potentilla reptans*), self heal (*Prunella vulgaris*), birdsfoot trefoil (*Lotus corniculatus*), suckling, and an abundance of small grass seeds. Of these, suckling clover

occurs in the greatest amount, over 20 per cent. and in one instance over 50 per cent. of this impurity having been met with in samples. With wild white clover fetching 15s. to 20s. per lb., and suckling clover not worth more than 1s. per lb., there is no denying the fact that suckling clover is a serious impurity in samples purporting to be wild white clover.

Mixtures of Alsike and White Clover.—About 90 samples described as "alsike and white" were tested. In only two cases did white clover preponderate over alsike in these mixtures, the amount of white clover present being usually from 20 per cent. to 30 per cent. of the bulk. The germination was quite satisfactory, that of alsike in mixtures being slightly above the average germination of alsike, whilst the germination of white clover was about 4 per cent. above the average of white clover samples. These mixtures, however, usually contained a large percentage of impurity. Moreover, 36 per cent. of the samples contained 1 per cent. and over of "injurious weeds," chiefly suckling clover, whereas only 3·2 per cent. of alsikes and 17·2 per cent. of white clovers contained this amount of suckling clover and injurious weed seeds proper. It should also be noted that the mixtures of alsike and white contained dodder in 6 per cent. of the samples, whilst alsike alone only contained dodder in under 1 per cent. of the samples, and white clover in just over 1 per cent. of the samples.

Trefoil.—The average germination of trefoil (64·2 per cent.) would seem to have been lower than the average for recent years. More of the current samples germinated below 50 per cent. than in the case of any of the other leguminous herbs or grasses, with the exception of meadow fescue and sainfoin. Trefoil was on the average cleaner than other leguminous herbs, and broken seed contributed very appreciably to the impurity. The nature of the included weed seeds indicated that the majority of the samples received were of British origin, French samples being, however, frequent. The outstanding impurity in trefoil was field madder (*Sherardia arvensis*) which occurred more often than in other herbage plants. Cut-leaved cranesbill (*Geranium dissectum*),ampions (*Silene et Lychnis* spp.) and docks (*Rumex* spp.) were also frequent, whilst ribgrass (*Plantago lanceolata*) was much less plentiful in trefoil than in the clovers. Trefoil seldom contained much "hard" seed, although two samples sent to the station in husk contained about 8 per cent. of such seed. This suggests that the process of "hulling" the seed tends to obviate "hardness."

Lucerne.—The average germination of lucerne (84.9 per cent.) was practically the same as that of Timothy, these two species attaining to a higher average than did any other herbage plants.

On the average the lucerne samples were relatively pure, broken seed contributing appreciably to the impurity. One sample, however, contained over 9 per cent. of trefoil. Ribgrass (*Plantago lanceolata*), wild carrot (*Daucus carota*), ox-tongue (*Picris echioides*) and *Setaria viridis* were the most abundant and frequent weed impurities.

The great majority of the samples were presumably of French origin, for, as well as ox-tongue (*Picris echioides*), such weeds as *Centaurea maculosa* and *Malva* spp. were of common occurrence. Dodder in small amount was present in 7 per cent. of the samples. There is a decided tendency to "hardness" in lucerne, for whereas the French red clovers gave an average of 2.6 per cent. "hard" seed, the average for lucerne was 6.3 per cent.

Sainfoin.—The average germination of these samples (53.2 per cent.) was not satisfactory; two samples proved incapable of germination, and 35 per cent. did not reach a germination of 51 per cent. It is noteworthy that the milled samples gave a slightly higher germination than the un-milled, whereas Biffen in 1912-1913 had found the opposite to be the case. On the average the French samples gave a slightly higher germination than did the English.

The purity of the majority of the samples was satisfactory. Burnet (*Poterium* spp.), however, occurred to an extent of over 5 per cent. in two samples; whilst soft brome (*Bromus mollis* et spp.) was too plentiful in some of the samples. Darnel (*Lolium temulentum*), cleavers (*Galium Aparine*) and campion (*Silene* et *Lychnis* spp.) were also met with.

Crimson Clover.—The average germination (81.4 per cent.) of crimson clover was satisfactory; a few poor samples were, however, received.

The chief impurities present in addition to broken seed were Campions (*Silene* et *Lychnis* spp.), ribgrass (*Plantago lanceolata*), cut-leaved cranesbill (*Geranium dissectum*), madder (*Sherardia arvensis*) and cleavers (*Galium Aparine*). Dodder (*Cuscuta* spp.) occurred in one (French) sample. A noteworthy feature was the negligible amount of "hard" seed in all the samples.

MISCELLANEOUS PLANTS.

(received in small numbers only.)

The average germination obtained in the case of a few species received in small numbers only is given in the table hereunder :—

TABLE X.

Maize	74.9	Mustard	91.3
Sunflower	93.0	Kohl Rabi	66.0
Buckwheat	91.0	Cauliflower	50.0
*Tomato	77.0	Broccoli	84.0
Lettuce	96.0	Yarrow	74.2
*Hemp	19.0	Chicory	53.2

* One sample only.

It is only necessary to remark that the majority of the maize samples received at the Station were of South African origin; a few of these contained over 5 per cent. of inert matter consisting of broken seed and remains of the cob. The highest germination of these samples was 100 per cent., and the lowest 6 per cent.

GERMINATION OF CERTAIN WEED SEEDS.

A few germination tests of certain weed seeds were made with the following results. The nature and germination of the sample from which they were obtained is given for comparison :—

Weed.	Germination per cent.	Occurring in per cent.
Soft cranesbill (<i>Geranium molle</i>) ..	94	White clover .. (77)
" " " ..	96	" " (84)
Cut-leaved cranesbill (<i>Geranium dissectum</i>) ..	94	Red clover .. (65)
Campion (<i>Lychnis</i> spp.) ..	89	Alsike .. (81)
Ribgrass (<i>Plantago lanceolata</i>) ..	73	Red clover .. (21)
Madder (<i>Sherardia arvensis</i>) ..	73	White clover .. (96)
Suckling clover	93	" " (72)
Crepis (<i>Crepis virens</i>) ..	62	Dog's Tail .. (58)
" " " ..	30	" " (66)
Cat's Ear (<i>Hypochaeris radicata</i>) ..	25	Perennial rye-grass (82)
" " " ..	42	" " (87)
Ox-eye daisy (<i>Chrysanthemum leucan- themum</i>) ..	25	Italian rye- grass (88)
Yorkshire fog (<i>Holcus lanatus</i>) ..	70	" " (78)
Soft brome (<i>Bromus mollis</i> et spp.) ..	88	" " (86)
" " " ..	98	" " (78)
Rat's-tail fescue (<i>Festuca bromoides</i>) ..	90	" " (75)

Most of the above figures represent the average of three separate hundreds. It is interesting to note that in many cases the germination of the weed is better than that of the sample in which it is contained. As, however, the weed seeds were picked out by hand from the bulk samples a certain amount of "selection" probably occurred, and the figures given above must be taken as referring to good plump seeds. The results clearly indicate, however, that many of the commonly occurring weed seeds have a high germinating capacity even when present in comparatively poor samples of grasses and clovers.

SUMMARY AND CONCLUSIONS.

The particulars given in the body of the Report suggest that, in the interests of increased food production, the following points in particular demand the attention of farmer and seedsman alike.

Germination.—The fact that 71 samples, or approximately 1 per cent. of all the samples received at the Station during the season, germinated 5 per cent. or less, clearly indicates that much worthless seed is liable to get into the hands of farmers and to be sown with a view to crop production. It is evident moreover that a poor germinating capacity should be guarded against in the case of all varieties of seeds. It must in particular be emphasised that the germinating capacity of cereals is very deceptive, and it is an undoubted fact that wheat and oats especially should in all doubtful cases be subjected to a germination test before reliance is placed upon samples for seed purposes.

Certain kinds of seeds should be purchased with special caution with regard to germination; this is especially so in the case of kale, cabbage and allies, parsnip, carrot, beet, red alsike and white clovers, trefoil, sainfoin, cocksfoot and meadow fescue.

The quality of a few kinds of seed would seem to have been decidedly below the average of recent years, *e.g.*, vetches, English red clovers (the yearling samples being remarkable for an unusually poor capacity of germination), trefoil, meadow fescue, Timothy, scarlet runner and French beans. Mangold seeds were probably above the average.

Purity.—It has been emphasised that more attention should be given by farmers to the purity of cereals for seed purposes; the same is true of vetches which, like cereals, are sown in large quantities per acre, and which, even if containing less than 1 per cent. of weed seeds, may nevertheless be responsible for the introduction of many thousands of bad weeds on arable land.

The rye-grasses and red clovers are not only liable to contain excessive amounts of harmful weed seeds, such as soft brome (*Bromus* spp.) and Yorkshire fog (*Holcus lanatus*) in the former, and dodder (*Cuscuta* spp.), docks (*Rumex* spp.), wild carrot (*Daucus Carota*), cranesbill (*Geranium dissectum*) and campions (*Silene* et *Lychnis* spp.) in the latter, but, since they are sown in large amounts per acre, they are fruitful disseminators of weed seeds. White clover tends to be more impure than alsike clover and also contains more harmful weeds; excess of the small-flowered cranesbill (*Geranium molle* and *G. pusillum*) and sheep sorrel (*Rumex Acetosella*) should in particular be guarded against. It is probable also that the extent to which crepis (*Crepis virens*) occurs in crested dog's tail should receive more attention at the hands of the farmer and the seedsman than heretofore. Although it is an admitted fact that dodder is not of much significance when present in clovers sown in Scotland and the North of England, it must also be appreciated that, generally speaking, it is not practicable to clean seeds with a view to use in certain specified localities only. The fact that dodder occurred in 26.9 per cent. of all the red clover samples, and in over 80 per cent. of Chilian samples (largely used as these are in southern and northern counties alike) and was not absent from alsike, white clover, crimson clover, lucerne and Timothy, is evidence that sufficient attention is not yet paid to the elimination of this parasite.

The purity of grasses and clovers commonly used for ordinary rotation and short temporary leys will become a matter of increasing importance in proportion as the newly-ploughed grass land is gradually brought into normal rotation husbandry. The figures given in the Report are, unfortunately, evidence that much totally uncleaned, or but partially cleaned, seed is still used by farmers in the formation of rotation grass.

In this connection it is well to realise, moreover, that the process of cleaning bulks full of weeds is both expensive and wasteful of good seed. Farmers are therefore urged to take every precaution when sowing seed for the production of seed, to secure absolutely clean seed for the purpose, and to sow such seed on land that has been well cleaned. This is the most satisfactory and economical means of securing supplies of pure seed. Since, owing to the provisions of the Testing of Seeds Order,* the trade are undoubtedly paying an increased amount of attention to the purity of their seeds, the grower who can offer harvests free from weed seeds should attract the best prices from prospective buyers.

* See this *Journal*, July, 1918., p. 477.

The Country of Origin of Certain Seeds in Particular.—It has been shown in the case of red clovers that the highest purity and germination tend to occur in samples harvested elsewhere than in Britain. It is important, therefore, that the inherent value of British-grown clovers should be realised. Chilian and other foreign clovers undoubtedly give good results for one-year leys, but such trials as have been conducted indicate that the highest yields are frequently obtained from selected British stocks, and that these in many districts "hold" on the land longer than foreign clovers. Similarly, the fact that wild white clover has a much lower average germination than ordinary white Dutch clover must not prejudice farmers against the use of this all-valuable home product.

Onion growers, moreover, very generally consider that the best yields are obtained from home-grown seeds, and similar views are held as to sainfoin and rape, particularly in certain districts. These points demand emphasis, since seed production may be regarded as almost a world-wide industry; the climate of Britain, also, is by no means the most suitable for the maturing and harvesting of all classes of seeds. The Testing of Seeds Order will have largely failed in its purpose if it tends to encourage the importation and use of foreign seeds simply on account of their high germinating capacity. Seeds should be selected for their productive capacity; the choice of samples, therefore, demands a careful weighing of the rival claims of (a) variety, (b) country or district of origin, (c) germination, and (d) purity. The Testing of Seeds Order now makes it possible for purchasers to take all those matters into consideration; the influence of the Order upon increased food production is therefore dependent in the last resort upon the farmer making the best use of the information necessarily supplied to him.

The Storage of Samples.—The condition of a large number of yearling samples sent to the Station by both farmers and merchants shows that in many cases not enough attention is paid to the condition under which seeds are stored. Several samples were rendered practically worthless as the result of the ravages of mice; while some samples were badly attacked by beetles, mites and other insects.

The Board are much indebted to Mr. T. J. Jenkin, B.Sc., Mr. S. P. Mercer, B.Sc., Mr. R. Robson, M.Sc., and Miss K. Sampson, B.Sc., for their valuable assistance at the Station during the height of the busy season. Thanks are also due to the Heads of the Agricultural Departments and College Authorities at the University College of North Wales, Bangor, the Armstrong

College, Newcastle-upon-Tyne, the East Anglian Institute of Agriculture, Chelmsford, and the University of Leeds, for kindly releasing the above members of their respective staffs for the period over and above the University vacation.

Directions with reference to sending samples to the Station and the fees to be paid are set out in—(a) Food Production Leaflet No. 47 (for the use of farmers) and (b) Notice to Seedsmen S.T.8 (for the use of seedsmen). Copies of the former may be obtained on application to the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1, and of the latter on application to the Director-General, Food Production Department, 72, Victoria Street, London, S.W. 1.

SOME RECENT INVESTIGATIONS ON THE FOOD OF CERTAIN WILD BIRDS.

WALTER E. COLLINGE, D.Sc., F.L.S.,

Carnegie Fellow, 1916-18; and Research Fellow of the University of St. Andrews.

I.—INTRODUCTION.

THE study of economic ornithology is one that has been woefully neglected in this country, and the value of many of the earlier contributions to the subject is seriously minimised owing to the methods employed in estimating the food contents of the crop and stomach.

At the present time any factor that bears injuriously upon agriculture is worthy of more than ordinary attention, for it is evident that for some years to come our home-grown food supply will be a vital necessity to the people of this country.

The relationship existing between the feeding habits of wild birds and agriculture is as yet only very imperfectly realised. On the one hand we have a rapidly decreasing number of insectivorous birds, and on the other a large increase in the number of the few species that are known to be injurious. It is obvious that in the interests of agriculture, the former should receive every protection and encouragement, whilst against the latter a very firm repressive policy should be adopted.

The conditions which it is desirable to establish, and which should be ever borne in mind when considering protective or repressive measures, have been very succinctly summarised by the late Professor F. E. L. Beal, who writes (3)* :—"A

* The numbers in brackets refer to the numbers of the references in the Bibliography on p. 690.

careful examination of the circumstances in which birds have done harm leads to the belief that the damage is usually caused by an abnormal abundance of a species within a limited territory. In such cases so great is the demand for food that the natural supply is exhausted and the birds attack some of the products of garden or orchard.

"Economically considered, birds are simply natural forces, and it should be our purpose to ascertain how they may be turned to our greatest advantage. The best economic conditions are probably fulfilled when birds are numerous as species and moderately abundant as individuals. Under such conditions there will be a demand for food of many kinds, without excessive demand for any one kind. The most desirable status would seem to be such a relation of numbers and species between birds and insects that the birds would find plenty of food without preying upon useful products, while the insects would be held in such check that they would neither increase to a harmful extent nor be completely exterminated. The proper course to pursue, apparently, is to study the food habits of both birds and insects, to favour the increase of species which seem best adapted to preserve the proper balance, and to reduce the numbers of those that prey too greatly on the products of orchard or farm."

In other countries, where the study of this subject has reached a more intensive level, very stringent laws have been enacted, and the policy of protection for all species that are beneficial and the formulation of repressive measures for those that are injurious, has borne excellent fruit and more than justified the action of the State in maintaining its special departments for the study and investigation of this intricate problem.

That the problem is an intricate one few will deny, and the time has now arrived when individual expressions of opinion unsupported by facts, or investigations that take note of the food consumed in only particular months of the year, are no longer of service, for they rather hinder than help in arriving at a true estimate of the precise economic status that any particular species occupies.

Hasty generalisations on a subject presenting so many difficulties can only be productive of harm. As Mr. William Berry has recently, and very truly stated (4), "Newspapers teem with ill-informed letters and articles on this subject, and the remedial measures recommended would usually prove as futile as they are drastic."

In the past the subject has to a large extent been treated in a very casual and unscientific manner, and yet it is obvious that it is one that is vitally related to both agriculture and horticulture, and requires to be pursued along strictly scientific lines.

In my work on the food of certain British wild birds (9), published in 1913, I was able to treat of all but one of the species dealt with in the present investigation, but, unfortunately, the method of estimating the crop and stomach contents there adopted was that known as the numerical one, whereas the only one that affords scientific accuracy is that known as the volumetric method, and, with the exception of two species (the green woodpecker and the pheasant), is here used for the first time in this country in relation to the species treated of, nine species in all, which have been re-investigated during the intervening five years.

Hitherto some of these species have been condemned and others have wrongly been regarded as beneficial, but the evidence forthcoming is not convincing. In cases of this kind surely it is necessary, to use the words of Lord Kelvin, that we should be able to measure what we are speaking about and express it in numbers, otherwise our knowledge is of a meagre and unsatisfactory kind.

In the investigation now set forth, an attempt has been made to state in definite figures the actual percentages of the different kinds of food consumed by each species during a whole year.

The total number of adult specimens examined is 3,670, obtained during each month of the year, and 595 nestlings.

II.—METHODS.

Considerable controversy has taken place as to the value of the different methods employed for estimating the food contents of birds' stomachs. On the one hand we have the system of percentage valuation by bulk and on the other the numerical system. The former is that adopted by the United States Biological Survey, whilst the latter has been used by a few workers in the United States and almost entirely by British workers.

It is not necessary here to assert the superiority of the volumetric method over that of the numerical or gravimetric methods. The various objections that have been raised have been dealt with in a very able paper by McAtee (19). The reader who wishes to follow the subject further may consult this together with a paper by the writer (13).

Bryant (5) in his work on the Western meadowlark made an attempt to arrive at the average volume of food taken by this bird, by determining the volume of food contained in a large number of stomachs in cubic centimetres and taking an average volume. This allowed the recording of each stomach as being of average volume, over the average, or below the average.

The same writer so clearly and forcibly states the case for this combination, that I quote him at length. "Three methods," he writes, "may be used in estimating the quantity of food in a bird's stomach. First, the articles may be counted; second, they may be weighed; or third, they may be estimated by volume.

"The first method, although important as giving an idea of the bird's economic value by showing the number of injurious insects or seeds destroyed, fails to take into account the difference in size of the different articles, and does not show the relative amounts of each kind. The second method has been generally disregarded because of its impracticability. The third or volumetric method allows of a balance of the inequalities of size and best portrays 'the ratios each element bears to the others.'

"By the numerical method, 50 ants would be placed against, say, 6 ground beetles. A computation made by the percentage-by-volume method would doubtless show that these two kinds of food represented only 3 and 26 per cent., respectively, of the whole food. Hence the idea furnished in the first case (a ratio of 50 to 6) is a misleading one. Numbers of one insect cannot be balanced against the numbers of another insect. As each bird of the same species has a certain average stomach capacity, the ratio of each element to this average capacity gives the most accurate idea of the relative proportions of each kind of food."

In estimating the percentages of the different items of food I have followed the system in use at the United States Bureau of Biological Survey. The percentages have been estimated separately for each stomach contents in accordance with the ratio of each element to the total contents. The percentage of sand, gravel, etc., was first set down in relation to the gross contents, and the remaining food items then considered as 100 per cent. Empty or almost empty stomachs, or others for various reasons judged abnormal, have been rejected.

III.—SPECIES EXAMINED.

1.—MISSEL THRUSH (*Turdus viscivorus*, Linn.).

During recent years this species has increased very rapidly, particularly in the South, and is more and more becoming a fruit-eater. There is now ample evidence to show that for at least four months in the year it does considerable harm in fruit-growing districts.

Post-mortem Records.—Fifty-two specimens have been examined; Of the total food consumed during the year, animal food forms 55 per cent. and vegetable food 45 per cent. The greatest proportion of animal food is consumed in May and June, viz., 78·5 and 75·5 per cent. respectively. The various items are as follows :—30·5 per cent. consisted of injurious insects, 23·0 per cent. of which were beetles and beetle larvae, 5·0 per cent. the larvae of lepidoptera, and 2·5 per cent. of leather-jackets, crane flies and eggs of crane flies; beneficial insects, mostly beetles and beetle larvae, were present to the extent of 4·5 per cent.; and 1·0 per cent. of neutral insects. Earthworms form a large proportion of the diet, constituting 14 per cent. for the year, the highest percentage being reached in April and May, which was 23·0 per cent. in both months; slugs and snails represent 3·5 per cent.; and miscellaneous animal matter, such as spiders, millipedes, etc., 1·5 per cent.

Of the 45 per cent. of vegetable food, wild fruits and seeds were present to the extent of 24·0 per cent., and 16·5 per cent. were certainly cultivated fruits, whilst the remaining 4·5 per cent. of miscellaneous vegetable matter consisted of grass, fragments of flowers, etc. (*Fig. 1*).

Summarising these figures we find that 35·5 per cent. of the total food consumed during a whole year is beneficial, 43·5 per cent. is neutral, and 21·0 per cent. is injurious (*Fig. 2*).

Food of Nestlings.—Only sixteen nestlings were examined. The whole of the food consumed was of an animal nature, and consisted of 38·5 per cent. of lepidopterous larvae, 16·5 per cent. of coleopterous larvae and fragments of a few small beetles, 19·0 per cent. of diptera and dipterous larvae, 15·5 per cent. of earthworms, and 10·5 per cent. of slugs. Of the insect content, 72·0 per cent. consisted of injurious insects, and 1·0 per cent. of each neutral and beneficial insects.

Conclusion.—In spite of its depredations in fruit-orchards this bird must at present be regarded on the whole as beneficial, for the number of injurious insects and slugs that it destroys more than counterbalance the injuries it inflicts. I must frankly admit that my estimate in 1913 (9) was imperfect, when, judged by the numerical method of estimating its food, I wrote "For four months in the year it does more harm than is counterbalanced during the remainder of the year." The improved and more accurate method of estimating the nature of its food now shows that statement to be wrong, and I am glad to be able to correct it.

Fruit growers in the South undoubtedly suffer much more from the activities of the Missel Thrush than growers in the more

FIG. 2.—Diagram summarising Injuries, Benefits, etc., of the Missel Thrush.

FIG. 1.—Diagrammatic Representation of the percentages of Food of the Missel Thrush.

northern parts of the country, for during the winter these birds migrate southwards, and, finding plenty of fruit trees, they remain there and cause considerable damage.

In certain localities the bird is undoubtedly too numerous, and in all probability a reasonable reduction is justifiable in such areas, but its general destruction would be a distinct economic loss to the country.

2.—HOUSE SPARROW (*Passer domesticus*, Linn.).

Sonnini, writing nearly a century ago, stated that sparrows lived "only in society with man, dividing with him his grain, his fruit, and his home; they attack the first fruit that ripens, the grain as it approaches maturity, and even that which has been stored in granaries."

"Its history," says Skinner (20), "begins with that of man, and it is referred to by Aristotle and many other European writers on natural history who followed him; in fact, there is reason for believing that it was known to people of whom we have no written history. When writing was invented the sparrow was selected for the hieroglyphic symbolising enemy, and proofs of its destructive habits have been cited by certain authors showing that it has been the enemy of mankind for more than five thousand years."

There is a very general, but entirely mistaken, opinion that the House Sparrow feeds largely upon insects. During the nesting season I have shown (10) that the food fed to the young birds, and in all probability most of that taken by the parents, consists mainly of insects, worms and slugs, but during the remainder of the year it is chiefly grain of some kind.

The late Professor C. V. Riley, the most eminent and experienced American economic entomologist of his day, was of opinion that this was "a destructive bird, worthless as an insect killer," while Judd (18) states "The English sparrow is the most highly granivorous bird on the farm. Grain . . . formed 86 per cent. of the food of the adults." Forbush (14) writes "Being a small bird, it necessarily eats many insects, but it lives more on grain and less on insects than any of the native birds that it supplants, and is one of the few species that deserves no consideration at the hands of the farmer." Skinner (20) remarks, "The house sparrow . . . has been known for ages as one of the worst of feathered pests." Gurney (16), Russell (16), Coues (16), Miller (16), Barrows (2), Ormerod and Tegetmeier (22) and many others have similarly condemned this bird.

The house sparrow is still with us and more numerous than ever, and its habits are the same as they were a hundred years ago. For 50 years at least the "sparrow question" has been debated in and out of season, and the bird has been condemned by practically every individual who has investigated its feeding habits. Its depredations are deplorable in the extreme, whilst the financial loss which it occasions amounts to some millions of pounds sterling per annum.

I have frequently expressed my opinion upon this bird and my only reason for including it in the present investigation is in order to give the results of an analysis of the food by the volumetric method.

FIG. 3.—Diagrammatic Representation of the percentages of Food of the House Sparrow in Agricultural Districts.

Post-mortem Records.—Upwards of 1,200 specimens have been examined and these have been divided into three series, viz. :—

1. Adults from agricultural districts.
2. Adults from fruit-growing districts.
3. Nestling sparrows.

1. *From Agricultural Districts.*—The total animal food consumed during the year amounts to 10.0 per cent., and the total vegetable food to 90.0 per cent. Of the former 5.0 per cent. consists of injurious insects, and 5.0 per cent. of miscellaneous animal matter of a neutral

have" and "at present the attitude of all farmers must be one of extermination."

FIG. 5.—Diagrammatic Representation of the percentage of Food of Nestling House Sparrows.

3.—ROOK (*Corvus frugilegus*, Linn.).

The economic status of this species still remains a matter of controversy in spite of the many investigations that have been made of its feeding habits.

Year.	Cereals.	Potatoes & Roots.	Miscellaneous- Vegetable Matter.	Seeds.	Insects.			Earthworms.	Slugs, Snails, and Millipedes.	Eggs, Field Mice, and Young Birds.	Total Animal Food.	Total Vegetable Food.
					Injurious.	Beneficial.	Neutral.					
1913 ..	34.5	14.5	6.5	4.0	24.5	3.5	4.5	4.0	2.4	1.6	40.5	59.5

1916 ..	38.5	12.5	6.5	4.0	22.5	3.5	4.5	4.0	2.4	1.6	38.5	61.0
Averages	35.1	13.4	6.1	4.4	23.9	3.5	4.6	4.4	3.2	1.4	41.0	58.9

I have set forth in considerable detail the results of an investigation made in 1908-09 (6). Further work carried out during the past four years only serves to emphasise the fact that with the present abundance of this species it is much more harmful than beneficial.

A summary of the four years' work is shown in the table above, the stomach contents being estimated by the volumetric method.

The details of the various kinds of food have been frequently set forth. I have not thought it necessary, therefore, to schedule them again. Fig. 6 sufficiently indicates the percentages of the totals and averages.

All the evidence collected with reference to this species, *i.e.*, post-mortem examinations of the stomach contents and field observations, leaves no doubt as to the true economic position

FIG. 6.—Diagrammatic Representation of the percentages of Food of the Rook.

it at present holds. Any policy of extermination or even general destruction would, in my opinion, be a most short-sighted and unwise one on the part of agriculturists; at the same time reasonable repressive measures are very desirable, for so long as rooks are as numerous as at present, they will continue to be a source of considerable harm to cereal and root crops.

4.—SKYLARK (*Alauda arvensis*, Linn.).

The Skylark has long occupied an ambiguous place as regards its economic position. We know that it feeds largely upon injurious insects and their larvae and the seeds of weeds, but

FIG. 8.—Diagram summarising Injuries, Benefits, etc., of the Skylark.

FIG. 7.—Diagrammatic Representation of the percentages of Food of the Skylark.

at the same time it has frequently been observed damaging autumn-sown wheat and other crops. What, however, has not been known was the exact proportion of its total food that was injurious, beneficial, or neutral. Hammond (17) in his investigation of the feeding habits of this species sums up as follows: "The bulk of the food consists of weed seeds; this is eked out in the summer months by insects, and in the winter by pieces of leaf, for the most part of crops. . . . the damage to leys and wheat is done for the most part by the migratory birds, but the damage to 'small seeds' is probably done by the birds breeding here. The conclusion reached is that, on the whole, the lark is beneficial; but, owing to the injuries done at certain seasons of the year, there is no reason why it should be specially protected, although its wholesale slaughter is to be deprecated."

The results obtained by the present investigation prove the skylark to be considerably more beneficial than injurious, the bulk of its food consisting of *weed seeds and injurious insects*.

Post-mortem Records.—Sixty-nine specimens have been examined, or an average of 5.75 for each month of the year.

Of the total food consumed in a year, animal food forms 46.0 per cent., and vegetable food 54.0 per cent. Of the former, 35.5 per cent. consists of injurious insects, 3.4 per cent. of neutral insects, and 2.5 per cent. of beneficial insects; earthworms constitute 2.0 per cent., slugs 1.0 per cent., and miscellaneous animal matter 1.5 per cent.

As already stated the vegetable food consists largely of weed seeds, the actual percentage being 43.5; of grain, there is 9.5 per cent., and leaves of crops 1.0 per cent. (*Fig. 7*).

A summary of these different items shows (*Fig. 8*) that 50.5 per cent. of the total food consumed is of a neutral nature, 36.5 per cent. beneficial, and only 13.0 per cent. injurious.

Food of Nestlings.—The nine nestlings examined showed that the whole of the food was of a beneficial character, consisting of caterpillars, aphids, and remains of beetles and their larvae, including wireworms.

Conclusion.—This volumetric analysis of the skylark's food no longer leaves us in doubt as to the true economic position it should occupy. The injuries it does by damaging seed corn and other crops are far outweighed by the benefits it confers in destroying injurious insects. Very truly has it been said that "in nearly all cases, the misdeeds of birds are much more manifest than the benefits they confer upon us."

No difficulty should be experienced in holding in check the migratory birds arriving in the autumn when found to be doing harm.

5.—GREEN WOODPECKER (*Gecinns viridis*, Linn.).

In 1915 I published a short report (11) upon the economic status of this species, and in view of the national importance

of forestry in this country, the precise position of so beneficial a bird cannot be too widely known.

Post-mortem Records.—The number of specimens examined was 78, and the whole of the food consumed throughout the year was of an animal nature. Injurious insects formed 75.0 per cent., 20.0 per cent. consisted of ants, and the remaining 5.0 per cent. was unidentifiable remains of insects, including a single ladybird beetle. There were also two spiders (*Fig. 9*).

Conclusion.—A species that destroys so large a percentage of injurious insects would need to have some very serious and proved shortcomings before we could regard it as injurious,

FIG. 9.—Diagrammatic Representation of the percentages of Food of the Green Woodpecker.

and observations made in all parts of the country, from 1913 to the present date, fully confirm the fact that trees which are sound are seldom, if ever, attacked by woodpeckers.

To my mind there can be no question as to the value of the woodpecker in relation to forestry, and it deserves every protection.

6.—SPARROW HAWK (*Accipiter nisus*, Linn.).

Writing many years ago Yarrell (23) very truly stated that this is "the only bird-of-prey which the game-preserver nowadays need fear."

I have elsewhere shown (12) that game-birds are exceedingly beneficial from the standpoint of the agriculturist, and we must, therefore, very carefully weigh and interpret the evidence forthcoming as to the economic position of the sparrow hawk. It has long enjoyed an unenviable reputation in the poultry-yard, and it is certainly not beloved by the gamekeeper.

Post-mortem Records.—One-hundred and nine specimens have been examined. The total food content for the year shows that 97·5 per cent. consists of animal food and 2·5 per cent. of vegetable food. Of the former, 16·5 per cent. consists of game-birds, 9·5 per cent. of poultry, 6·5 per cent. of ducklings, 4·5 per cent. of insectivorous birds, and 4·5 per cent. of beneficial insects, or a total of 41·5 per cent. of an injurious nature. Against this must be placed 19·5 per cent. of black-birds, sparrows, and wood-pigeons, 15·0 per cent. of injurious insects, and 6·5 per cent. of mice, making a total percentage of benefits of 41 per cent. Neutral insects account for 5·5 per cent., and miscellaneous animal matter, 9·5 per cent. It was not possible to say whether this belonged to the injuries or benefits, so we have proportioned it, giving 5·5 per cent. to the former and 4·0 per cent. to the latter. There was also 2·5 per cent. of miscellaneous vegetable matter (*Fig. 10*).

Thus we have 47·0 per cent. of injuries, 45·0 per cent. of benefits and 8·0 per cent. of a neutral nature. (*Fig. 11*).

We have now to interpret these facts, or in other words consider the economic value of the different food items.

Whilst the destruction of such injurious birds as sparrows, wood-pigeons, and blackbirds is a point in the birds' favour, this item can scarcely be regarded as equivalent to a similar percentage of game-birds, poultry, young ducks, or insectivorous birds. Moreover, practically all of the latter group, excepting the insectivorous birds, were young birds or chicks, whereas, with the exception of a few wood-pigeons and blackbirds, all the former were adults. The loss or injury is therefore considerably in excess of the benefits, but not to the extent that is usually supposed. In the matter of insects 25·0 per cent. was found, but beneficial species formed 4·5 per cent., and neutral species 5·5 per cent., the actual injurious species amounting to only 15·0 per cent.

Conclusion.—After very carefully considering the above facts we are of opinion that the injuries this bird inflicts are considerably in excess of the benefits it confers, in consequence of which we cannot advocate any protection for it.

7.—KESTREL (*Falco tinnunculus*, Linn.).

On the assumption that all hawks are injurious, the Kestrel or Windhover has been persecuted for very many years, and in certain districts it has become fairly rare. Yet in spite of all that has been said and written against it, it is one of the most useful birds we have in its relation to agriculture. All who have investigated its feeding habits have been compelled to admit that the good it does far outweighs any harm it occasions during a very brief period of the year.

FIG. 11.—Diagram summarising Injuries, Benefits, etc., of the Sparrow Hawk.

FIG. 10.—Diagrammatic Representation of the percentages of Food of the Sparrow Hawk.

Yarrell (23) states that mice form the principal part of its food, and that it appears to obtain them by dropping suddenly upon them. Montagu says "he never found any feathers in the stomach of this species; but it is certain that it does occasionally kill and devour small birds, and at times the young of larger ones. The remains of frogs, coleopterous insects, their larvae, and earthworms, have been found in their stomachs"; and Selby, on the authority of an eye-witness, has recorded the fact of the Kestrel hawking cockchafer's late

FIG. 12.—Diagrammatic Representation of the percentages of Food of the Kestrel.

in the evening. The observer watched the bird through a glass and "saw him dart through a swarm of the insects, seize one in each claw, and eat them while flying. He returned to the charge again and again. I ascertained it beyond doubt, as I afterwards shot him."

Archibald (1) has drawn attention to three facts about kestrels which should not be lost sight of, viz., "The first is that they very frequently bring up their young within easy reach of hand-reared game without taking a single chick, but, notwithstanding the temptation, continue to lead a life of harmless utility. Secondly, it is only during a very brief period

FIG. 13.—Diagram summarising Injuries, Benefits, etc., of the Kestrel.

of the game-birds' existence that any danger need be apprehended from the windhover, for it will not touch them except during their helpless infancy. Thirdly, throughout the rest of the year the kestrel does incalculable and unmixed good, by the destruction of hosts of field-mice and injurious beetles. The value of farm produce thus saved from destruction is almost beyond estimation. It is, therefore, a short-sighted policy to exterminate such beautiful and useful birds because they do a certain amount of harm, that harm being confined to a very few weeks in the year."

Post-mortem Records.—An examination of the stomach contents of 80 specimens shows that animal food forms 99 per cent. of the total food consumed during the year, and vegetable food 1.0 per cent. only. Of the former 64.5 per cent. consists of mice and voles, 8.5 per cent. of sparrows, blackbirds, and thrushes, 6.0 per cent. of nestling birds, 16.5 per cent. of injurious insects, 2.5 per cent. of earthworms, and 1.0 per cent. of frogs (*Fig. 12*).

The only portion of this food that can possibly be placed against the kestrel is the 6.0 per cent. of nestlings, part of which consisted of game-birds. The remaining 89.5 per cent. is all in its favour, and 4.5 per cent. is of a neutral nature (*Fig. 13*).

The injuries occasioned by mice and voles are only too well known to need comment, but the total loss in food products and that due to damage must be considerable.

The damage done to young game-birds is trivial, when one considers the nature of the remaining food. Indeed, supposing the kestrel destroyed no mice or voles and obtained this 64.5 per cent. of food from

neutral animal and vegetable matter, it would still be a valuable bird and worthy of protection, for it destroys 16.5 per cent. of injurious insects (mostly beetles, beetle larvae, and the caterpillars of certain Noctuid moths, such as the "Cabbage," the "Heart and Dart," and "Turnip Dart.") In addition to these it takes a certain toll of sparrows and blackbirds.

Conclusion.—Whilst no one wishes to see the ancient game laws, which protected the Kestrel, revived, it is a bird certainly deserving of very strict protection; and if certain individuals will persist in destroying a species that is so beneficial, they should be compelled to pay dearly for their foolishness.

8.—WOOD PIGEON (*Columba palumbus*, Linn.).

The Wood Pigeon has long been known as an injurious species, but from time to time there are those who will vigorously defend it, as if it were a friend rather than a foe to the agriculturist. This attitude invariably arises from an imperfect knowledge of the feeding habits of this species. An examination of the crop contents of a bird shot in May or June, or indeed in any odd month of the year, but very imperfectly indicates the nature of the food throughout the year; and

FIG. 14.—Diagrammatic Representation of the percentages of Food of the Wood Pigeon.

FIG. 15.—Diagram summarising Injuries, Benefits, etc., of the Wood Pigeon.

certainly gives no idea as to the ratio which one item of food bears to another. In one case such an examination might lead one to suppose that the species was very beneficial, whereas it might be a most injurious one, and in regard to another might lead us to condemn an undoubtedly beneficial species.

Post-mortem Records.—The stomachs and crops of 428 specimens have been examined. Of the total food content for the whole year 96.5 per cent. consisted of vegetable food and 3.5 per cent. of animal food. Of the former 38.5 per cent. was composed of grain, viz., 16.5 per cent. of barley, 12.5 per cent. of wheat, 8.0 per cent. of oats, and 1.5 per cent. of rye. Clover constituted 9.5 per cent. of the total food content, roots and potatoes 8.5 per cent. and beans and peas 5.5 per cent. Fruits, seeds, leaves and roots of weeds and various plants and grass represented 34.5 per cent. Of the animal matter, earthworms accounted for 2.0 per cent., slugs and snails 1.0 per cent., and fragments of insects 0.5 per cent. (Fig. 14). In other words, 62.0 per cent. of the food was injurious to agriculture, 36.5 per cent. of a neutral nature, and only 1.5 per cent. beneficial (Fig. 15).

Let us proceed to interpret these figures. Assuming that a Wood Pigeon requires on an average about $2\frac{1}{2}$ oz. of food per day or 57 lb. per year, then, according to the percentages of the total food bulk consumed in a year, it would roughly eat $35\frac{1}{2}$ lb. of grain, clover, roots and pulse, $20\frac{1}{2}$ lb. of weeds, grass, earthworms, etc., and about 1 lb. of slugs, snails, and insects. Taking the injurious element as of the first importance, 100,000 birds would consume nearly 1,584 tons of such food in a year.

Yarrell informs us that in East Lothian between 1863 and 1870 over 130,000 birds were shot without materially affecting its numbers.

From all parts of the country we hear of flocks varying from 5,000 to 20,000. What the total census for the United Kingdom must be it is difficult to say, but the number must be a very large one.

There can be no question as to the economic position this bird occupies, and every means should be taken to destroy it.

9.—LAPWING (*Vanellus vulgaris*, Bechst.).

I have previously dwelt upon the apathetic indifference displayed by agriculturists towards this species (9), but its fate must not be permitted to rest in their hands, unless we wish to see its numbers gradually but surely reduced. It would be impossible to overestimate its value to agriculture.

Post-mortem Records.—Sixty-nine specimens have been examined. Of the total food content consumed during the year 89.0 per cent. is animal food and 11.0 per cent. vegetable food. Of the former, injurious insects form 60.0 per cent., neutral insects 4.0 per cent., slugs and snails 10.0 per cent., earthworms 10.0 per cent. and miscellaneous animal matter of a neutral nature 5.0 per cent. Six per cent. of the vegetable food consists of weed seeds and 5.0 per cent. of miscellaneous vegetable matter. Thus 70.0 per cent. of the food is of a beneficial nature and 30.0 per cent. neutral (Figs. 16 and 17).

The three chief items constituting the insect food are wireworms, beetles and beetle larvae, and leather jackets.

FIG. 16.—Diagrammatic Representation of the percentages of Food of the Lapwing.

Conclusion.—For some years to come the taking or killing of the birds or the eggs should be prohibited throughout the year

FIG. 17.—Diagram summarising Benefits, etc., of the Lapwing.

IV.—SUMMARY AND CONCLUSION.

As the result of an examination of the stomach (and crop, where present) contents of 3,670 adult birds and 595 nestlings, embracing nine species of wild birds, we are of opinion :—

1. That the volumetric method or percentage by bulk is the only reliable one for estimating the nature of the food and a bird's true economic position.
2. That the numerical method is highly misleading and unsatisfactory.
3. That of the nine species of wild birds treated—
 - a. Two are distinctly injurious, viz., the House Sparrow and the Wood Pigeon.
 - b. Two are too numerous, and consequently injurious, viz., the Rook and the Sparrow Hawk.
 - c. One is locally too numerous, viz., the Missel Thrush.
 - d. Four are highly beneficial, viz., the Skylark, the Green Woodpecker, the Kestrel, and the Lapwing.
4. That in the interests of agriculture it is very desirable that strong repressive measures be taken against the species mentioned in section a, and for the time being all protection withheld from those species mentioned in sections b and c, whilst every protection should be given to the four species mentioned in section d.

5. Finally, as a result of this investigation, we are of opinion that all of the commoner species of wild birds require re-investigating so far as their food and feeding habits are concerned, and their various food items worked out and estimated by the volumetric method.

REGULATIONS AFFECTING THE REARING, FEEDING AND DISPOSAL OF HORSES.

Sale and Purchase of Horses: Sale of Horses Order, 1917.—The occupier of an agricultural holding may not sell or part with the possession of any horse which is used or is capable of being used for the cultivation of the holding, except with the authority of a licence.

A farmer who wishes to sell or transfer a horse which is not required by him for work on his farm, should make application to the Agricultural Executive Committee of the county in which his holding is situated for the necessary licence.

Such licences will only be granted in cases in which the County Executive are satisfied that the horse is surplus to the requirements of the holding, and the licences may contain such conditions as the Committee think desirable.

A farmer who wishes to purchase a horse for the cultivation of his holding, does not require a licence to purchase, but in his own interests should satisfy himself that the animal he proposes to buy, if coming from an agricultural holding, has been duly licensed for sale and that the conditions of the licence are complied with.

By the Horses Order, 1918, the Controller of Horse Transport is given the power of taking possession on behalf of the Board of Trade of any horse which is not being used wholly or mainly in agriculture, either absolutely, or by way of hire subject to such terms, other than compensation, as he may direct.

Purchase of Feeding Stuff.—Priority certificates are now issued for horses engaged in agricultural work, and application

for such certificates, if required, should be made to the Live Stock Commissioner of the area in which the applicant resides.

Restrictions in the Use of Feeding Stuffs.—All horses (includes mares, geldings, colts, fillies, ponies and mules) are allowed the free use of roots, grass and green forage crops. Horses may only be fed with feeding stuffs of a cereal nature unfit for human food (grains, beans, peas, and products thereof), and hay, straw and chaff in strict accordance with the scale of rations laid down below. It is a penal offence to exceed the scale of rations allowed.

It is forbidden to feed horses, or allow horses to feed on growing crops of wheat, barley, oats, and dredge corn in such a way as to prevent the crop reaching maturity. The restriction here given does not apply to winter sown barley.

The use of straw for bedding purposes is also forbidden. Oat straw, in particular, may only be used for feeding purposes. All horse chaff mixtures must be sold by weight, must contain not more than two-thirds by weight of chaff, and such chaff must not contain more than four-fifths of its weight of hay.

Necessity of Adopting a Scale of Rations for Farm Horses.—Although horses used specifically for agricultural purposes are exempt from the operation of the Rationing of Horses Order, it is strongly urged upon all owners of farm horses to adopt the scale of rationing as laid down for heavy working horses. The allowance given will be quite ample for the horses' needs, and horses so rationed will keep in good condition and carry out their work quite efficiently. The serious shortage of feeding stuffs renders such a course imperative, as unless the farmer adopts a scale of rations for his own horses there will not be enough feeding stuffs left over to supply the needs of the town horse and pit pony.

Keeping of Records by Horse Owners.—All persons owning horses entitled to limited rations of hay, straw, chaff and cereal feeding stuffs must keep a record in writing showing :—

(a) In the case of hay, straw or chaff :—

1. The number and classes of horses entitled to a ration.
2. The total maximum daily ration authorised by the Order.
3. The description and quantities of hay, straw and chaff fed to such horses each week.
4. The description and quantities of all hay, straw and chaff purchased and the date of purchase.

(b) In the case of cereal feeding stuffs :—

1. The number and classes of horses entitled to a ration.
2. The total maximum daily ration authorised by the Order.

3. The description and quantities of cereal feeding stuffs fed to such horses each week.
4. The description and quantities of all cereal feeding stuffs purchased to the date of purchase.

NOTE.—For the purposes of the above records the following quantities of other feeding stuffs shall be regarded as equivalent to 10 lb. of oats: maize $7\frac{1}{2}$ lb.; beans or peas 9 lb.; dried brewers' grains 12 lb.; bran 13 lb.

Maximum Daily Rations allowed to Horses.—

Cereal Feeding Stuffs in Terms of Oats.

Class of Horse.	In hard and continuous work.	When not in hard and continuous work.	Hay and Straw or Chaff.
1. Horses used exclusively or mainly for agricultural purposes	Excluded from the operation of the Orders.		
2. Stallions used exclusively for stud purposes ..	Excluded from the operation of the Orders.		
3. Horses in the possession of, or used exclusively for the purposes of, the Army Council, the Air Board, and the Admiralty	Excluded from the operation of the Orders.		
4. Horses used solely or mainly for trade or business purposes :—			
a. Heavy dray and cart horses and trotting vanners	14 lb.	10 lb.	16 lb.

335 ; the Hay and Straw Order, 1918, No. 631 ; the Horse and Poultry Mixtures Order, 1917, No. 1173 ; the Growing Grain Crops Order, 1918, No. 402 ; the Cattle Feeding Stuffs (Priority Supply) Order, 1918, No. 7 ; the Horses Rationing Order, 1918, No. 410 ; and an Army Council Order dated 9th May, 1917.

(This article is also issued as Leaflet No. 9 of the Joint Committee of the Board of Agriculture and the Ministry of Food. Copies may be obtained free and post free on application to the Secretary, Joint Committee, Board of Agriculture and Ministry of Food, 6A, Dean's Yard, Westminster, S.W. 1.)

POULTRY ON ALLOTMENTS AND GARDEN PLOTS.

Under Orders made by the Food Controller the use for the feeding of Animals and Poultry of wheat, rye, barley, rice and dredge oorn which are fit for manufacture into flour for human food is prohibited.

By paying special attention to the management of their poultry, cottagers, allotment holders and others may increase the home production of food, with profit to themselves and advantage to the nation.

A great many people could keep a few fowls for egg production who do not. By feeding surplus garden stuff, and scraps of "waste" food from their own and neighbours' kitchens to their fowls, householders can reduce their bills for poultry food. With proper housing and systematic management, laying hens give a profitable return for the cost of their keep and the small amount of time and attention which is necessary.

The following notes are of a general character. More detailed information on particular points is given in the various leaflets on poultry keeping issued by the Board.

Suggestions.—1. Under present conditions poultry-keepers will best serve the national interest by producing eggs rather than table poultry, for two reasons : (a) because the shortage is more keenly felt in regard to eggs than table fowls, as the country is more dependent upon imported eggs than upon imported poultry ; and (b) because foodstuffs can be employed to greater advantage in the production of human food in other directions than in rearing purely table poultry.

2. To obtain the maximum number of eggs, fowls should not be kept beyond the end of their second laying season. It is

better to replace the stock every other season than to mix hens and pullets, this practice often proving more economical than securing fresh pullets each year.

3. Only hens which have laid well as pullets should be used for breeding purposes. It is even more important to use a cock from a good laying strain.

4. Eggs for hatching should always be from well-matured stock at liberty or in very large runs.

5. A male bird is unnecessary in most small yards; better stock can be obtained at a cheaper rate by the purchase of sittings each year from a reliable breeder, than by using home-produced eggs.

6. Hatching should not be later than March for the heavier and April for the lighter breeds.

7. It is important that whether chickens are reared naturally or artificially they should be given fresh ground and be kept apart from the older birds, or they will be liable to disease, or fail to make satisfactory growth.

8. It is better to purchase pullets in the autumn rather than to attempt to rear them when the ground available is limited.

9. Cockerels not required for breeding should be sold as soon after their sex is distinguishable as possible. Old hens and superfluous cocks should also be sold. Room will thus be left for the more productive stock, and the food bill will be reduced.

10. Care should be taken not to overstock the ground available for these purposes. Half-a-dozen hens may often be profitably kept on a small area, say, 120 sq. ft., whereas double the number would involve loss. Overcrowding is not good management.

11. If knowledge of poultry-keeping is limited, only a few birds should be kept at first. As experience is gained, the stock of poultry may be increased.

Suitable Classes of Poultry.—For occupiers of allotments and gardens fowls are the most suitable kind of poultry to keep.

Residents near open land such as commons should breed runner ducks or geese. Where there is plenty of rough grazing these birds are profitable, as they forage for the greater part of their food, and are naturally grazers. Ducks, geese and turkeys are unsuitable for allotments and gardens.

Area of Land Required for Poultry.—Poultry are more healthy and productive with an open run, however small this may

be, and the number kept must be determined by the area available. For permanent occupation 50 fowls per acre may be regarded as sufficient. The occupier of an allotment with a good building may keep as many as 100 fowls on a $\frac{1}{4}$ of an acre, provided he is a skilful manager of poultry, but at the end of a year the ground should be vacated and cropped. Such a practice will only be successful in skilled hands.

From 6 to 12 hens should be the number generally kept on small runs by the garden poultry-keeper who can use an area of from 36 to 150 sq. yd. Half-a-dozen hens can be kept upon a plot 20 ft. by 6 ft., provided the soil is frequently dug over and renewed by fresh earth. In any case the ground should be kept as sweet as possible by sweeping, turning over and renewing the soil in small runs.

How to Use the Ground.—Apart from the danger of disease, poultry will not thrive upon tainted soil. Results will be less good each year of the occupation of one spot which is at all heavily stocked, unless constant labour and attention to the soil are exercised.

By far the best plan is to divide the ground into 2, 3 or 4 parts, and use each plot in succession for the birds, while the ground unoccupied is fully cultivated and cropped.

The manure on the parts successively vacated will largely increase the crops grown if the ground is suitably cultivated.

Only laying hens should be kept upon the part devoted exclusively to poultry. If chickens are reared they may be placed upon another section, but should on no account be reared in the pen with the hens, since this practice makes it impossible to obtain the best results from either the hens or chickens.

House and Runs.* Upon allotments and gardens where it is necessary to confine birds in wire runs, the runs should be so erected that they may readily be moved to fresh ground. The wire may be fastened to posts with wire nails bent over rather than with staples; this will facilitate removal by unhooking, and will result in less damage to the netting.

The simple form of house is best, but it is always worth while to provide sufficient cover to afford a dry scratching shed in addition to the roost. The roost and shelter may be combined as one compartment or be separate, each method having certain advantages, and it is largely a question of the material and site available as to which it is better to adopt.

* See also Leaflet No. 294 (*Poultry Houses and Appliances for Allotment Holders, Cottagers and Others*).

Where garden walls can be utilised to form part of the building it is usually preferable to have two separate compartments, especially if the run is limited, while a building of the combined type is better in the open, where there is more freedom for the birds.

The house with a shelter below is not to be recommended, as it involves lack of light and air, and is not convenient for cleaning the shelter, which is generally of little use as a scratching shed, and only utilised by the birds for dusting purpose.

A combined house, 7 ft. by 8 ft. with an average height of 5 ft., is a most suitable size for 12 to 15 birds. The open-fronted type is generally to be recommended, but in order to get the full benefit of the light with this facing S. or S.E., and without the disadvantages from driving rain in dull weather when the shelter is necessarily more often used, not more than 2 ft. of the front should be boarded up. This necessitates 18 in. to 2 ft. of glass, and a narrow hood at the top in order to keep out the wet and allow sufficient light. Less expensive glass, such as "hammered plate" serves the purpose better than canvas shelters and screens, which are often recommended, but are less durable and in the end are more expensive.

In a house already constructed and faulty in this respect, a top light will frequently improve matters.

The perches are best placed across the back of the house with a dropping board beneath, 2 ft. above the floor. Nest boxes placed so that only a dim light shows the interior, and preferably raised above the floor, prevent the risk of the evil habit of "egg eating."

A dry floor is essential, damp earth or litter in the house being a great deterrent to egg production.

When the house and shelter are in separate compartments, they should always be so constructed that the birds have access from one to the other without having to pass into the open. The trap door between may then be left open, and the birds are enabled to be down scratching in the early morning without being exposed to inclement weather. In the roost 2 sq. ft. per bird is sufficient area, and in the scratching shelter not less than 4 sq. ft. per bird.

It is essential that light should be given in the roost, and both house and shelter should be ventilated to keep the building sweet and airy without a direct draught beneath the birds when perching.

Existing sheds can often, with slight alterations, be well adapted for poultry, and no special type need be strictly adhered to if the principles of light, air and cleanliness are followed.

Hints for Practical Management.—Success in egg production is as much due to good management as to prolific stock.

Cleanliness is one of the most important factors and should be practised in regard to the house, the bird, and the food and water. A little thought and ingenuity will evolve methods securing the desired end with the minimum of labour.

Parasites.—There should be no red mite or hen fleas in properly-kept houses, and lice on the fowls can be kept down by rubbing sulphur into the feathers in spring and summer, and providing facilities for a dust bath.

Light and Ventilation.—The value of ample light in the shed cannot be overestimated, and if the house is well ventilated the birds will keep bright and healthy.

Exercise.—Exercise induced by keeping the birds well occupied is of great importance. Several inches of dry litter should be kept on the floor of the scratching shed. It should be of a light nature, such as straw chaff, dry leaves or bracken, in which the corn given is scattered for the birds to seek; the burying of grain in soil or the use of material of a heavy nature for the birds to turn over is a mistake often made. Such heavy work is not conducive to a large egg yield, although for breeding stock it is good to keep the fowls in hardy, muscular condition.

Feeding.—Plenty of fresh green food, shell and grit, have great effect in increasing egg production. Green food, unless chopped into small pieces, is best suspended to enable the birds to peck pieces off more readily; stale stumps and leaves should not be allowed to lie about. Odd scraps of flesh or fish, *e.g.*, rabbit offal or fish skins, are valuable food, and should be saved and given after cooking; there is little fear of over feeding an active type of fowl if the food given is of a correct nature to meet the bird's requirements.

Advice.—At the present time advice as to the selection, housing, and management of poultry is likely to be especially useful. In counties where an Inspector in Poultry Keeping has been appointed application for his advice and assistance should be made through the Agricultural Organiser or through the Secretary of the County Education Committee.

(This article is also issued as Leaflet No. 310, revised in August.)

THE difficulty of obtaining suitable feeding stuffs has become more intense and may be expected to remain so at least until the harvest is secured, when supplies of tail corn will again be available, though possibly in limited quantity. The past quarter has been characterised by shortage, not only of suitable grain for feeding, but also of suitable and adequate supplies of offals for mash feeding. This has resulted in a very considerable rise in price of those cereals or cereal products that are obtainable and not prohibited for poultry feeding—maize meal, for example, is now 25s. per cwt. as against 22s. at the date of the last quarterly report.

Notes on Poultry Feeding.

(From the Harper Adams Agricultural College, Newport, Salop.)

Owing to its price clover meal still offers attractions as a mash ingredient for the poultry keeper, provided that the sample is of good quality, for, unfortunately, no recognised standard of quality for this material yet exists.

Realising the seriousness of the shortage of millers' offals which have formed the basis of mash feeds, a feeding test of bulk foods from new sources has been made at the College with some success. While it was not found possible to maintain egg production at the high standard that it was possible to achieve with a pre-war ration, that experiment showed that it is possible to substitute some of the sharps or bran—both of which contain a fair proportion of fibre—for some readily procurable bulk food of vegetable origin.

Quite the most promising results were obtained with bracken feed, which possesses the advantage of being abundant in many parts of the country that are often ideal for poultry stock. Growing, as it does, in a dense mass, it is collected with a minimum of labour, and with normal weather conditions it is easily sun- or air-dried.

Analyses have shown the importance of properly sieving the material to remove the coarser portions of the fronds, in which the fibre content is much higher than in the finer portions.

Further work is in progress which has for its object the determination of the best time for cutting the bracken. From the results obtained it is found to be advisable to cut early before the centre stems become hard, and, though the loss in weight during drying is greater, the lower percentage of indigestible fibre more than compensates for this loss. In bracken cut young, the quantity of such fibre will amount to about 10 per cent. after milling and sifting, as against 40 to 50 per cent. in the mature fern. The young fern does not contain the amount of dust that is to be met with in the older bracken.

The bracken after cutting should be sun dried, turned, and handled just as clover hay, and the greener it can be stacked (provided it is thoroughly dried) the better the resulting sample. It should be carefully stacked and thatched and allowed to remain for a little time before being chaffed and put through any form of grinding mill.

A sifted sample of such meal has the following composition :— dry matter, 87 per cent., containing albuminoids, 5.65; carbohydrates, 58.8; oil, 2.9; and ash 7.8 per cent., as compared with clover meal, albuminoids, 14.4; carbohydrates, 42.6; oil, 2.6; and ash, 10.5.

A suitable ration would be: bracken meal 2 parts, fish meal 1 part, sharps 4 parts. In using the bracken meal it is advisable to scald it well and use the other meals of the mixture to dry off.

At this time of the year vegetables are abundant and the utmost use should be made of all waste produce. Mixed pig meals are still obtainable in parts of the country and may well be used as the basis of the mixture where very small quantities of other foodstuffs can be bought. As an example of a useful mixture the following may serve :—

Pig meal	3 parts.
Maize meal	1 part.
Sharps	1 "
Bran or clover meal, or bracken meal	1 "
Fish or meat meal	1 "
Vegetables	—

In using such a mixture the best results will be obtained where the grain fed can approximate to from a half to an equal weight of the mash.

THE following Notes of an interesting experiment, made under unfavourable conditions, of the cheap feeding of laying hens have been communicated to the Board by a

Experiment on correspondent :—

Cheap Feeding of

Laying Hens.

"No grain or grain product whatever was fed to the hens during the 4½-months tests. The food was a vegetable waste, say cabbage, 2 parts; carrots, turnips, and onions, together, 1 part; potatoes 6 parts, plus 1 part fish meal, fed as boiled. A cabbage to peck at was occasionally hung up.

The food ratio was kept as nearly 1 to 3 as possible and tested by analysis occasionally.

The hens were kept under ordinary backyard conditions and no grass surface was available. Comfortable but inexpensive accommodation was provided for roosting and a small covered area for scratching, the balance of yard surface being gravel or ashes. The health of the hens has distinctly improved during the period of the test.

On 14th February, two hens—A and B—were purchased from a local dealer at a cost of 7s. each, understood to be on sale for killing

purposes, and a third hen, C, was given for test purposes, free of cost, by a friend who was hopeless of getting eggs from her.

Hen A, which was of the White Wyandotte type, though possibly not pure, started to lay on the 9th March, and during the month of March gave 18 eggs, missing on the 10th, 12th, 14th, 19th and 25th. In April she gave 24 eggs, missing on the 4th, 9th, 14th, 19th, 20th and 23rd, while in May she gave 26 eggs, missing on the 4th, 14th, 21st, 25th and 30th. In June she gave 22 eggs, missing on the 4th, 8th, 12th, 16th, 19th, 23rd, 26th and 29th.

Her weight has varied a few ounces down, and latterly up again to her original weight.

Hen B, mongrel type, started to lay on the 16th March and gave 12 eggs, missing on the 17th, 20th and 24th. In April she gave 15 eggs and was broody from the 6th to the 19th inclusive and missing on the 28th. In May she gave 11 eggs, missing on the 1st and 30th, and being broody from the 9th to the 26th inclusive. In June she gave 17 eggs, missing on the 29th and 30th, and being broody from the 8th to the 16th inclusive.

Hen C, mongrel type, was in poor condition and when she came had every appearance of liver trouble. She gave two eggs only in April, one on the 20th and one on the 30th. In May she gave 25 eggs, missing on the 3rd, 9th, 13th, 19th, 23rd and 30th, and in June she gave 22 eggs, missing on the 8th, 13th, 17th, 18th, 22nd, 24th, 27th and 30th.

Some Wyandotte chickens which had been reared to three months old on corn and soft mash have, for the past month, been fed on the same mixture of waste vegetable material with fish meal, and on weighing the cockerels on 1st July, they averaged $3\frac{1}{2}$ lb., the pullets averaging $2\frac{1}{2}$ lb., and all appear to be in excellent growing condition.*

Uses for Fish Meal.—The value of fish meal as food for stock was hardly realised in this country before the War, and practically the whole production, some 30,000 tons, was exported to Germany, where

it was much appreciated as a pig food. In point of fact, fish meal is a highly-concentrated food, the albuminous content of which makes it particularly valuable at the present time,

when imported concentrated food is scarce. It should be given in small quantities, as an adjunct to foods in which carbohydrates predominate. The quantities which can be given to stock were stated in a special leaflet (No. 8*) issued by the Board of Agriculture some time ago as follows: pigs $\frac{1}{4}$ to $\frac{1}{2}$ lb. per day; cattle 2 lb. for every 1,000 lb. live weight; sheep 1-1oth to 1-5th lb. for every 100 lb. live weight; chickens not more than 5 per cent. of total food. The high albuminous content of fish meal, as compared with other feeding stuffs, is shown in the following table:—

	Per Cent. Digestible.			Food Value, Taking Linseed Cake at 100.
	Protein.	Fat.	Carbo- hydrates.	
Ground nut cake ..	45.2	6.3	21.1	102
Linseed cake ..	26.7	9.3	30.1	100
Rice meal ..	6.8	10.2	38.2	90
Brewers' grain, wet ..	3.5	1.5	8.6	17
Feeding barley ..	8.0	2.1	57.8	89
Fish meal ..	54.0	4.0	—	78

Fish meal is being used increasingly for pig and poultry feeding; but there has been some hesitation about its use for other stock, partly

* This leaflet is no longer issued.

on the ground that it contains a quantity of salt, and, in the case of dairy cattle, because it was believed that the milk might be tainted. Experience goes to show that, in cases where the milk has been found to be tainted in fact, this has been due not to consumption of the meal, but to contamination from the hands of cowmen who handled the meal and also acted as milkers. An excessive amount of salt is a serious consideration, and the point is now being met by the Association of Fish Meal, Fish Guano and Fish Oil Manufacturers, who have decided to standardise a meal made from white fish and white fish offal without any admixture of herring material. The constituents are to conform to the following analysis: albuminoids, 55 (minimum) per cent.; phosphates, 16 per cent.; oil 5 per cent.; and salt 4 per cent. Herring meal will also be made.

The output of the fishing industry has, of course, been heavily reduced under war conditions, and there has been a corresponding reduction in meal and other by-products. Even so, a substantial quantity of this albuminous food is available.

Bracken Roots for Pigs.—Investigations have been made by Professor James Hendrick into the possible utilisation of bracken, hitherto looked upon as a noxious weed which is destroying much pasture land, especially in Scotland.* He states that the fronds which appear above ground in spring are not relished by stock, and, though said in their young state to be wholesome, they appear to be poisonous when fully grown. Outbreaks of bracken poisoning take place from time to time when stock, driven by hunger, or for some other reason, eat large quantities of the matured frond.

A few inches below the surface of the ground the bracken forms an underground creeping stem or rhizome, which is popularly known as the bracken root. In well-stocked bracken land there is a very large crop of such rhizomes, branching rods about the thickness of a finger and many feet in length. In these the bracken lays up a store of food, which it draws upon to support growth in the spring. The rhizome is in its richest state in winter, when the fronds have died down. In spring its food stores become somewhat depleted when growth starts, but there is always a considerable store of starch and other food materials. Experiments made in Scotland on measured pieces of ground have shown a crop varying from 11 tons per acre to over 60 tons per acre. Where the 11-ton crop was obtained the land was not very thickly stocked with bracken, and the rhizomes were washed free from earth before being weighed. The crop of over 60 tons was obtained on land very thickly stocked, and the rhizomes were not washed. They contained about 25 per cent. of earth and dirt, so that the crop of clean rhizomes amounted to over 45 tons per acre.

An analysis of rhizomes from the average of six samples collected in different parts of Scotland between the beginning of April and the beginning of June is as follows:—

<i>Average Analysis (Six Samples).</i>								Per cent.
Moisture	77.2
Oil2
Albuminoids	2.4
Soluble Carbohydrates	12.8
Fibre	5.4
Ash	2.0
								100.0

* See also this *Journal*, March, 1918, p. 1446. and May, 1918, p. 233, as to the value of bracken as fodder.

The samples gathered at the beginning of April before growth had begun were better than the average. They contained only 75 per cent. of moisture and about 15 per cent. of soluble carbohydrates. On the other hand, those collected at the beginning of June, when a considerable growth of frond had already taken place, contained nearly 80 per cent. of moisture, while the soluble carbohydrates had diminished to about 11 per cent. The soluble carbohydrates consist largely of starch, though other substances are present.

A number of experiments have been made with pigs, and it has been found that both breeding and feeding pigs will eat the rhizomes readily, except in cases where they have been receiving a rich diet of concentrated foods. It has also been found that, where pigs are turned out unringed on bracken land, they root up the rhizomes for themselves and eat them eagerly. In the past efforts have been made to eradicate bracken by cutting or otherwise destroying the fronds. If pigs can be fed on bracken land a double purpose will be served. Food will be provided for the pigs in the rhizomes of the bracken, and the land will be cleared. On the other hand, it is only in exceptional circumstances that it will pay to dig up bracken rhizomes in order to feed stock. As a rule, bracken land is hilly and stony or full of the roots of trees.

Experiments in feeding cattle and other stock on bracken rhizome meal are in progress. (*National Food Journal*, 10th July, 1918.)

SULPHATE of ammonia may be stored in two ways, either in bags or loose in a heap. Whichever method is adopted, the building in which it is stored should be dry and free from dampness. Buildings easily penetrated by rain, or with damp walls or floors should be avoided.

**Storage of Sulphate
of Ammonia on
Farms.**

If stored in bags, a platform under which the air can circulate should be constructed with a space about 6 in. from the floor, and the sacks piled carefully one on top of the other, lengthways, with mouths turned outwards. Care should be taken to leave a space all the way round the pile. This not only facilitates loading, unloading and packing, but also allows air to circulate all round. If the building of the platform presents any difficulties the sacks may be piled on one or more layers of hurdles. Before constructing the platform, the floor underneath should be covered about 3 in. deep with some dry substance, which will absorb any moisture which may drain off from the sacks.

The best substances for this purpose under ordinary circumstances are castor meal, rape meal, bone flour or raw bone meal, as they can be used afterwards as fertilisers; but in determining whether it is profitable or not to use them at the present time, regard must be paid to the price at which they are obtainable. Failing these a layer of dry earth, sand, peat

moss, or sawdust will suffice. It is not advisable to use superphosphate for this purpose. Neither chalk, lime, nor basic slag should on any account be employed, as they "set free" the ammonia and thus cause wastage.

In this connection it may be remarked that unless brought into contact with running water in which it will be dissolved and washed away, sulphate of ammonia will not lose any of its fertilising value, however long it is stored. Except in the case of the "neutral" quality,* which is practically dry, there may be a slight loss in bulk during storage owing to evaporation of moisture, but this will not exceed 1 to 2 per cent., and does not affect the fertilising value, as there will be no loss of ammonia or nitrogen.

Farmers will find it to their advantage to secure the "neutral" quality wherever possible, as this contains practically no free acid and will, therefore, not attack or rot the bags. With ordinary qualities of sulphate of ammonia in which free acid is present, there will always be a tendency for the bags to rot during storage, and it is in view of this that some farmers prefer to empty out the sacks on receipt and store the sulphate in bulk.

The same principles apply to storing in bulk as to storing in sacks. The floor should be covered about 6 in. deep with one of the absorbent substances indicated above, and if the heap touches the sides of the building, the eaves should be carefully inspected from the inside to see that there is no discharge of water from leaky spouts. The building and its walls and floor should, of course, be perfectly dry.

The sacks should be well shaken out, and if subsequently required to contain other materials, they should be washed out immediately in water.

Before applying to the land, care should be taken to see that the sulphate of ammonia is not in a lumpy condition, and it will be found advantageous to pass it through a $\frac{1}{4}$ -in. riddle, breaking the lumps down with a piece of wood.

This procedure will not be necessary if "neutral" sulphate can be secured, as this quality does not cake nor contain lumps, but remains free like sand. Sulphate of ammonia in this condition can be applied through a drill. When a small amount is being applied unmixed with other manures it is usually

* Sulphate of ammonia containing less than .025 per cent. of free acid is known commercially as "neutral" sulphate of ammonia.

found advantageous to mix it with an equal quantity of sifted earth or sand to help even distribution.

(This article is also issued as Food Production Leaflet No. 53, copies of which may be obtained free and post free on application to the Secertary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W. 1.)

THE following Note was issued by the Joint Committee of the Board of Agriculture and the Ministry of Food on 10th August :—

The Farmer and the Dung Heap. Every farmer knows full well that successful farming depends on, among other things, good tillages, clean land, and the right use of dung. Very few farmers need teaching how to keep the land clean or how to prepare the land for crops: they would be poor farmers if they did! Yet how many of them neglect that little gold mine of the farm, the dung heap, and through carelessness that needs only a little trouble to avoid, allow the best part of the dung to go into the nearest drain instead of where it can do most good, on the land.

Let us put it into figures. Before the war, farmers in the United Kingdom used about 27,000,000 tons of farmyard manure containing 185,000 tons of nitrogen, or more than seven times as much nitrogen as was put on to the land, in the form of artificials. With bad storage and making, as much as *half the nitrogen* in the dung can easily be lost. Even with care a certain amount must be lost, but by taking precautions the farmers of the United Kingdom could easily save the equivalent of 100,000 tons of sulphate of ammonia, and with sulphate of ammonia at its present price, a little thought will show the farmer how much money he is losing every year through want of sufficient care in handling and storing the dung. If the muck can be spread green, all well and good, but most systems of cropping necessitate the use of well rotted or half rotted dung. The question then arises: "How am I as a good farmer to make the most of what dung my stock produces on my own farm?" The points to be considered are very simple and few, and it is urged on every farmer to go through them one by one and see if there is any possibility of improvement. The questions to be answered are :—

- (1) Is the dung made in covered yards, and if so, is the spouting and roofing good, or is half the goodness of

the dung lost at every good storm through a broken water spout or leaky roof?

- (2) If made in open yards, is the dung carted out as soon as possible and tightly clamped into as compact a heap as possible? Some careful farmers even go as far as to protect the half finished clamps with straw thatched hurdles, and nearly all of them cover the heap with a layer of earth when finished.
- (3) In the case of the dairy herd, is the manure thrown out from the cowsheds either kept well protected from the rain or carted straight out on to the land, or is it thrown out into the open so as to be almost worthless when spread?
- (4) Last but not least; is a *liquid manure tank* kept wherever possible? The liquid portion of the manure is a very valuable fertiliser, and in Denmark, special care is taken of the liquid manure, which is generally carted out on to the grass and pumped over the land *in early morning before the dew is off the grass*.

The points given are so obvious that the lay mind considers them trivial, but, as every farmer knows, success in farming depends on the attention to the little details which the ordinary man is apt to miss.

THE increasing difficulties of efficient distribution of fruit and vegetables through the London and provincial markets, owing to the abnormal conditions now prevailing, render it imperative in the public interest, to avoid waste of road and rail transport.

**Distribution of Fruit
and Vegetables
through the London
and Provincial
Markets.**

Growers, railway companies, salesmen and others concerned, therefore, should conform with the following rules regarding the distribution of produce:—

1. Full Loads to One Consignee.— Growers should co-operate in collating their produce, so far as practicable, in full truckloads for one consignee in one market, thus avoiding unnecessary splitting up of the loads between various consignees, which delays delivery to the market, and wastes labour and cartage strength.

When this course is adopted, one of the senders should act as the nominal consignor, for the purpose of obtaining the advantages of the reduced railway rates, where they are

provided, for such consignments. Local Committees of growers in each area should be formed to carry out this recommendation.

2. Overnight Advances of Forwardings.—Senders should advise the railway station authorities overnight of the approximate quantity of produce they expect to forward the following day (weather and other circumstances permitting).

3. Produce to be Sent to the Nearest Markets.—The demands of the nearest local market should be supplied first, not only to relieve congestion in the redistribution markets, but also to prevent waste of transport.

4. Fruit for Preserving.—Fruit intended for pulping, or jam making should not be consigned to a market, but to the order of the consignee, so that it may be delivered direct from the station to factory, thereby reducing the demands on both transport and labour.

5. Provision of Labour for Loading.—In view of the serious shortage of labour, the local committee of growers should lend every assistance to the railway in securing prompt loading of local produce at country stations.

6. Labelling Odd Packages.—All odd baskets, mats and bags of produce sent by rail, must be fully and clearly labelled.

7. Returnable Empty Packages.—The economical distribution of empty packages is of great importance owing to the shortage of supply. To obtain speedy return of these empties :—

- (a) Bushels, half bushels and peck baskets must be tied in bundles of 8, and each bundle labelled with the name of the consignee and the station.
- (b) Arrangements should be made, as far as possible, for empties to be brought together, in order to make full loads to the various destination stations, irrespective of the number of consignees at such stations.
- (c) The practice of sending empties to country stations *on the chance* of finding growers who will fill them, must cease.
- (d) Whenever possible, empties should be returned direct to the growers or producing centres.
- (e) Growers and others in country districts must remove empties promptly after their arrival at the railway station, and store them properly when not required for immediate use.

(This article is also issued as Food Production Leaflet No. 52.)

THE following information is extracted from *The National Food Journal*, 28th August, 1918 :—

Full details of the scheme for the distribution of the 1918 potato crop are printed below.

1918 Potato Crop : It should be noted that this scheme does not apply to seed potatoes sold for planting.

Details of the Distribution Scheme.

DIVISION OF COUNTRY INTO ZONES.

1. Great Britain will be divided into (a) areas which will have no surplus potatoes for export, but will require in most cases to import potatoes from other parts of the country ; (b) areas which will have a surplus of potatoes for export to other parts of the country.

N.B.—Scotland will be regarded as one area. There will be 20 zones in England and Wales, nine being surplus areas and 11 deficit areas. A list of the zones is given. It will be noticed that each zone is contained within the boundaries of a Food Control Division.

DEFICIT ZONES.

(a) **The Potato Control Committee.**—2. In every deficit zone a Potato Control Committee will be appointed under the chairmanship of the Food Commissioner or his representative. This Committee will include :—

- (i) Representative dealers and growers.
- (ii) A Divisional Potato Inspector appointed by the Vegetable Supplies Branch, but attached to the Divisional area and under the discipline of the Divisional Food Commissioner.
- (iii.) A railway transport officer, who will be appointed by the Director-General of Storage and Transport.

This Committee will be associated with an official clearing-house in each zone, and the Secretary of the Committee, who will be in charge of the clearing-house and also the executive officer of the Committee, will be appointed from the trade by the Ministry of Food.

(b) **Functions of Clearing House.**—The functions of the clearing-house will be :—

- (i.) To publish and enforce general rules laid down by the Ministry of Food, e.g., for securing that better keeping varieties of potatoes are reserved for later consumption.
- (ii.) To make and enforce any local additional rules found necessary in the zone for similar purposes.
- (iii.) To issue transport permits where necessary, and deal generally with all transport difficulties (road, rail and ship).
- (iv.) To take deliveries of, and pay the grower for, any potatoes which the Food Controller is liable to purchase, but which cannot be disposed of otherwise under the scheme.
- (v.) To collect the indents for imported potatoes and give the necessary orders to the supplying zones.
- (vi.) To advise on claims by growers on the Ministry of Food for damage other than normal wastage.

(c) **Functions of Potato Control Committee.**—

- (i.) To receive and deal with complaints from traders that they cannot obtain sufficient potatoes.
- (ii.) To receive and deal with complaints from growers that they cannot dispose of potatoes which should be put into consumption.

- (iii.) To deal with any complaints and disputes between growers and dealers or between importers and exporters as to the grading of potatoes in their district.
- (iv.) To deal with any complaints from growers that they have been unreasonably required to load or from dealers that growers have displayed negligence in loading.
- (v.) To receive periodical statements of account from traders buying from producers in their area and to pass them to the Divisional Accountant for adjustment.
- (vi.) To issue licences authorising the direct purchase of potatoes from growers by retailers or large consumers who have been accustomed to buy direct.

(d) Control of Distribution in Deficit Zones.—The principal points in which the distribution of potatoes within deficit zones will be controlled are as follows :—

- (1) Only persons holding licences may deal in potatoes.
- (2) Growers will have to be paid within 14 days of collection the price fixed by the Joint Commission appointed by the Ministry of Food and Board of Agriculture.
- (3) Any rules laid down by the Ministry or by the Potato Control Committee as to the restriction of good keeping varieties will have to be observed.
- (4) Retail prices for the public will be fixed.
- (5) The price of potatoes bought wholesale from a dealer will be fixed.

The machinery consequent on these restrictions is outlined in the succeeding paragraphs.

(e) Licensing of Dealers.—No one in the deficit zone will be allowed to buy potatoes from growers unless duly licensed. Licences will be issued mainly to existing dealers, but in certain cases they will also be issued to retailers and large consumers who can prove that they have been in the habit of buying direct from a grower in previous years.

Licences will be issued to dealers by the Ministry of Food on the existing recommendations from the National Federation and the Co-operative Wholesale Society, but they will be subject from time to time to any fresh recommendations or review on the part of the Potato Control Committee. Those licences to wholesale dealers will not carry with them any restriction on the quantities to be purchased provided that direct purchases will only be allowed within the zone for sale within the zone. Licences issued to retailers and large consumers accustomed to buy direct will be issued by the Potato Control Committee, and will in every case be for a quantity based on previous dealings. In all cases where the retailer or consumer purchases direct from a grower, the price paid by such retailer or consumer will be identical with the fixed price in the zone for similar purchases through a wholesaler. These licences will be subject to the payments by the holder of a fee (to be paid by instalments, if necessary) covering the difference between the fixed grower's price and the fixed wholesaler's price less any charges for extra haulage approved by the local Food Control Committee.

(f) Failure to Pay Grower.—In the event of a dealer failing to pay the grower within 14 days, the grower will complain to the Potato Control

Committee, and the latter, if satisfied that his claim is correct, will pay the grower and report the case to the Ministry of Food with a view to the dealer's licence being cancelled forthwith.

(g) Adjustment of Prices with Ministry.—Every dealer purchasing Potatoes from a grower will have to account to the Potato Control Committee for the purchase and resale, paying to the Ministry of Food any profit in excess of his fixed commission, and recovering any loss on the transaction. The dealer will pay the railway the actual freight charge, and account to the Ministry of Food for the difference between this and an assumed flat charge. The cartage and market dues will be fixed in each locality by the Food Control Committee.

(h) Free Trade in Zones.—Subject to the restrictions set out in the preceding paragraphs, there will be free trade within every zone, *i.e.*, there will be no restrictions as to the growers from whom the potatoes may be bought or the quantities in which they may be bought by a wholesaler. The Potato Control Committee will be given the necessary powers for compelling dealers in their district to collect potatoes from producers when satisfied that such stocks are in risk of serious deterioration unless brought into early consumption.

(l) Collection of Imports.—Dealers in any deficit zone who require to import potatoes will send in their individual indents to the Potato Control Committee indicating the quantity and grade (see para. 4) of potatoes required. The Potato Control Committee will send this collective indent to the chairman or chairmen of the zonal committee or committees assigned to them for the purpose of the Ministry of Food. The imports will be consigned to the Executive Officer of the Potato Control Committee, and will be distributed in accordance with arrangements made by this Committee.

SURPLUS ZONES.

(a) The Zonal Committee.—3.—In every surplus zone the Zonal Committee will be appointed under the chairmanship of a trader appointed by the Ministry of Food. This committee will include :—

- (i.) Selected collecting dealers within the zone nominated by all collecting dealers who hold licences.
- (ii.) A Divisional Potato Inspector appointed by the Vegetable Supplies Branch, but attached to the Divisional area and under the discipline of the Divisional Food Commissioner. The inspector will attend meetings of the committee, but will not have a vote.
- (iii.) A Zonal Accountant who will be a member of the staff of the Divisional Accountant, and therefore under the Divisional Food Commissioner. He will attend meetings of the zonal committee, but will not have a vote.
- (iv.) A transport officer appointed by the Director-General of Storage and Transport. He will attend meetings of the committee, but will not have a vote.
- (v.) Two representatives of growers within the zone nominated by the local branch of the National Farmer's Union.

(b) Functions of Zonal Committee.—The functions of the zonal committee in the surplus zone will be the same as those of the Potato Control Committee within the deficit zone so far as the internal trade

is concerned, with the exception that if any case of dispute arises which the zonal committee is unable to adjust, it will be referred to a divisional tribunal constituted as follows :—

1. The Divisional Food Commissioner as chairman.
2. The chairman of the zonal committee concerned.
3. A representative nominated by the National Farmers' Union for the district concerned.
4. A member of the headquarters staff of inspectors appointed by the Director of Vegetable Supplies.
5. The Divisional Accountant.

(c) Functions as an Exporting Committee.—Apart from the functions of the zonal committee as laid down in paragraph 2 for deficit zones, this committee will also be required to make the necessary arrangements for the export of potatoes to deficit zones in accordance with the general scheme laid down by the Ministry of Food. These functions will be performed in the following manner :—

The clearing-house in deficit zones will forward collective indents in the manner laid down in paragraph 2 (b) sub-section (v). The zonal committee at the beginning of the season will arrange for the collection of potatoes over specified sections of line or area of country within the zone by all the registered collecting dealers in the zone. Thenceforward the collective indent will be forwarded to the chairman of the zonal committee, who will distribute the order in accordance with the general scheme laid down by the zonal committee at the beginning of the season. The collecting dealers will advise the chairman of the zonal committee the quantity and grade of potatoes which have been placed on rail, and the grower will be paid by a cheque from the chairman's office, signed by the chairman and the zonal accountant jointly, and drawn on the Ministry of Food's account in the zone. The Secretary of the Potato Distribution Committee in the deficit zone will pay for the potatoes sent to that committee within 7 days of their arrival, and at the wholesale price laid down by the Ministry of Food according to grade. In sending in the collective indent the Secretary of the Potato Control Committee will indicate the stations to which consignments are to be sent and the grade which it is desired to have. So far as the stations are concerned, the chairman of the zonal committee will take care to see that instructions are carried out, but so far as grades are concerned will endeavour to meet the wishes of the exporting committees. The chairman of the zonal committee will retain the right to vary the quality according to local exigencies while preserving the quantity indented for.

All freight charges to the consignees' station will be paid from the office of the chairman of the zonal committee by means of free conveyance notes to be adjusted in his office.

(d) Distributing Committees in Consuming Areas.—In certain large consuming areas as laid down by the Ministry of Food, the importing functions of the Potato Control Committee will be devolved on special distribution committees, *e.g.*, each London market will have its distributing committee who, so far as importing is concerned, will forward their collective indent to the chairman of the zonal committee on exactly the same lines as is done elsewhere by the Potato Control Committee. It is only contemplated that those distribution committees

will be established in a comparatively small number of large consuming areas, and the chairman of a distributing committee should always *ex officio* be a member of the Potato Control Committee for the zone within which the consuming area is contained.

GRADES OF POTATOES.

4. There will be two grades of potatoes: Grade I. consisting of the varieties King Edward, Golden Wonder, Langworthy, What's Wanted and Maincrop, whilst Grade II. will include all other varieties.

Each grade will be sold to the consumer at a flat price throughout the country, and the initial prices to the consumer will be 1½d. per lb. for Grade I. and 1d. per lb. for Grade II., these prices being increased later in the season by an additional ½d. per lb. if this is found necessary.

It has also been pointed out that Scotland will be regarded as one area. The Potato Control Committee in Scotland will be replaced by the Central Allocation Authority, and this authority, subject to the final decision of the Ministry of Food, will have complete control both as regards internal and external trade. So far as internal trade is concerned, it will fulfil the same functions as the Potato Control Committees do in deficit zones in England. So far as external trade is concerned, it will combine the functions of the zonal committees in English surplus zones and of the divisional tribunal indicated in the preceding paragraphs. For the purpose of collecting potatoes it will utilise the organisation of the four Scottish associations.

It will probably be necessary to regulate internal railway transport in Scotland by dividing the country into several districts (which will not necessarily be coterminous with Food Divisions), and making each of these districts self-dependent for its supplies.

SUPPLIES FOR FORCES AND FOR FACTORIES.

5. The supplies of potatoes required for the Forces by the Forage Department and by the Navy and Army Canteen Board will be obtained by indent on the zonal committees and the Potato Control Committees, in order to secure that these supplies are not taken in such a way as to disorganise the system of supply for the civilian population or to cause an undue strain on railway transport.

Similarly the potato factories, which will all be situated in surplus zones, will obtain all their potatoes from the zonal committees in England, and from the Central Allocation Authority in Scotland. Supplies to factories must be regulated with reference to the needs of the population for ordinary consumption, and cannot be drawn independently.

UNLESS the Wart Disease of potatoes (*Synchytrium endobioticum*) can be checked, and that speedily, it bids fair within a very few years to become the most serious of the problems with which the potato-grower in this country has to deal. The Food Production Department of the Board of Agriculture have taken various steps to check the spread of Wart Disease; among them the prohibition of the planting

**The Immune Potato
Trials: Notes on the
New Seedlings.**

of non-immune varieties in various areas, an investigation of the cause and possible cure of the disease, and the trial of new seedlings believed to be immune from the disease.

The inspection of the trials of potatoes which are being tested at Ormskirk this year for immunity from wart disease took place during the week commencing 30th July. For several years these trials have been conducted on a small though steadily increasing scale. Obviously, it is a matter of vital importance to the potato-grower to have a recognised centre where new varieties or fresh selections may be tested for immunity under rigorous conditions. The Food Production Department issue annually for the guidance of potato-growers in areas infected with Wart Disease, a list of the potatoes that have successfully passed this test, and the verdict of Ormskirk on the resistance of a variety is authoritative.*

This year the scale of the trials has been enlarged. Not only has the total number of test plots risen to over 300, but a number of interesting points have been demonstrated. For example, a crop of an immune variety may be found which to the untrained eye looks uniform in type when growing in the field and which produces tubers of superficial similarity. These crops frequently contain "rogues" which are susceptible to wart disease and therefore render such "seed" quite unfit for planting in infected land.

The trials this year are arranged so as to illustrate points of this kind and to demonstrate the importance not only of producing a pure stock, but of keeping it pure by carefully removing the "rogues" each year. For instance, in one plot we find a carefully selected stock of a variety, and in the next plot are the "rogues" which were picked out by expert examination of the "seed" previous to planting.

Each year new seedlings are sent for trial, and the result is that the annual visit to Ormskirk has become a recognised and a pleasant addition to the duties of all the most experienced growers in Great Britain. The trials also appeal to the merchant, the farmer, and the allotment holder; and a day was set apart for the visit of representatives of each of these classes.

The production of a really good first early immune variety is a pressing need of the moment; and there is promise that successful efforts are being made to meet this need. The immunity of *Witch Hill* will probably be settled by this year's test, and *Arran Rose* (McKelvie), which proved immune as seedling No. 30 in the 1917 trials, is an interesting addition to the list. The future of *Dargill Early* was also the subject of lively discussion. *Arran Comrade* (McKelvie), second early, aroused considerable interest and seems likely to fill a useful place in its class.

It is proposed that the National Institute of Agricultural Botany, now being founded under the auspices of the Board of Agriculture, shall in future manage the Ormskirk trials, extend their scope and importance, and provide on the spot suitable buildings where the necessary research work may be carried out. The Board, the School of Agriculture of Cambridge University, and various Seed Trade Associations will be represented on the Council of the Institute, which is receiving enthusiastic and generous support from the trades concerned.

* See also Food Production Leaflet No. 21 (Wart Disease: Reports on the Immunity Trials at Ormskirk in 1915 16-17.)

The Growth of Allotments.—Up to 16th August, 289,853 allotment plots had been provided under the Cultivation of Lands Order, 1917.

During the second week of August three **Notes on Allotments.** local authorities arranged for just over 250 new allotments for next season. In each case, the authority had developed an earlier allotment scheme, and the new land is an addition to the areas already successfully cultivated in the respective districts. Chislehurst is acquiring 8 acres of new land; Withernsea, $3\frac{1}{2}$; and Elloughton and Brough, 6 acres.

Beckenham is achieving excellent results in assisting in the domestic food production of the country. The population is 34,000, of whom 7,900 are householders. Ninety per cent. of these householders are growing vegetables in their gardens; and 2,200 of them are allotment holders. At Shipston-on-Stour 93 persons are cultivating allotments, averaging over a quarter of an acre each, the total area being 27 acres. Moreover, 50 per cent. of the 344 householders are growing foodstuffs in their gardens. Seventy-five per cent. of the 800 householders at Tavistock have gardens which are being utilised for food growing. In addition more than half the householders have allotments averaging one-twelfth of an acre apiece. At Axminster about 60 per cent. of the 450 householders are cultivating kitchen gardens. Thirty per cent. of them are also allotment holders with about 10 poles each.

Home-saved Seed Potatoes.—Most potato growers are now agreed that "a change of seed always pays," but there are still sceptics who doubt the necessity of frequently renewing their seed supply from outside, instead of relying mainly on seed from their own crops. To these the following facts recently reported by the Food Production Department of the Board concerning the allotments at Ruskin Park, Camberwell, may be recommended for careful consideration. An inspection of the allotments showed that potato disease is very prevalent there; and in certain cases the crop will be a partial failure. In most of these cases home-saved seed was planted. On the other hand every plot planted with seed from Scotland or Ireland direct looks well, and none of them appeared up to the middle of August to have been affected by blight.

Assistance to Allotment Holders.—Although the Food Production Department is anxious, wherever possible, that would-be allotment holders should make their own friendly arrangements with the owners of land, its representatives are always ready to assist with advice in any case where difficulties may arise as to the amount of rent to be paid, or other matters. Recently, for instance, in Cheshire a representative of the Department succeeded in obtaining a reduction of rent from £42 to £32 10s. for 7 acres of land held by an allotment society. The Department has also been able to arrange for the continuance of tenancy in many instances where notice to quit had been served.

THE following is a Statement showing the Estimated Grants in Aid of Agricultural Research carried on at Research Institutions and other Research Centres and the nature of the

Grants in Aid of research work in respect of the financial **Agricultural Research.** year ending 31st March, 1919. The whole of the money expended was obtained from the Development Fund, with the exception of £450 of the £2,900 spent on research in fruit growing at the University of Bristol :—

The Women's Land Army.—The demands for women for threshing and potato lifting are larger than the numbers available, and a recruiting campaign has therefore been conducted in the holiday resorts of Kent and Sussex.

Women's Work on the Land.

Three new hostels were opened during the third week of August in Yorkshire, at Menthorpe, Parlington and Huddleston. In the case of the two latter places, they will develop a district which hitherto has been little touched by woman labour. The arrangements and prospects are hopeful, and orders for women are already being received.

The Oxted Tractor Training School for women is very successful. The women are taking a keen interest in their work. The mechanic in charge gives an excellent report of the ability of those women who have already passed through the school and speaks most encouragingly of the present students.

Women's Institutes.—Four new Institutes were started during the third week in August. The Essex Federation of Women's Institutes has undertaken the collection of blackberries in 200 parishes in connection with the scheme organised by the Food Production Department and the Ministry of Food.

An All-women Farm.—Last October the West Devon Executive Committee took over Great Bidlake Farm, Bridestowe, which is being used as a training centre for women. The farm, which consists of 134 acres, was formerly all in grass, but 73 acres have been ploughed up and are now carrying good crops of corn, roots and potatoes. All the work on the farm, with the exception of a little ploughing last autumn, has been done by women. The Food Production Department state that the buildings are in excellent condition and that the farmyard is one of the best kept in the West Country.

Women and Thatching.—Many farmers this year seem almost as troubled about the thatching problem as they are about the difficulty of getting in satisfactorily their generous crops. In various counties schemes for teaching women and lads how to thatch are being run with a greater or less degree of success. Generally, it has been found that fairly strong young women are able to do this work very well after a few weeks' training; indeed, in some of the Western Counties really excellent thatching has been done by women who knew nothing of it a short time ago. At Foleshill, near Coventry, two local farmers have arranged to put ricks at the disposal of the Women's Land Army for practical tuition in thatching. An expert woman thatcher will train 8 other women at a time. It is to be hoped that farmers will make arrangements as soon as possible for the employment of these women on the completion of their training. It is a curious fact that whilst on the one hand we hear farmers complaining that they do not know how they will get their ricks thatched this year, on the other hand a number of trained women thatchers have lately been unemployed, or rather have had temporarily to fill up their time at flax pulling. Thirty women have recently been sent to Somerset to be trained in the stacking of flax and in thatching.

THE Food Production Department have made arrangements for the selection by Professor Biffen of seed wheat of the following varieties harvested in 1918—
Scheme for the “Browick,” “Little Joss,” “Rivett,” and
Distribution of Seed “Yeoman.” Every endeavour is being
Wheat of the 1918 made to set a high standard of purity and
Harvest. quality for all seed distributed under this
 scheme. The Department will not supply farmers direct but have appointed agents from whom the seed wheat may be obtained, either direct by the farmer, or through a local corn merchant. Particulars of the names and addresses of the agents will be found in the advertisement appearing in this issue.

The following notes may serve as a guide in the selection of varieties :—

YEOMAN.—A new wheat raised at Cambridge in 1916. Ears medium length; white chaff; light red grain; straw medium length and very stiff. This wheat possesses high yielding and first-class milling properties and can be grown on all classes of soils. The supply of stock seed of this variety is very limited in quantity.

LITTLE JOSS.—Ears long ; chaff red ; grain red ; straw a little over the average length, but stands well. This wheat tillers very freely and matures early. It has been successful on every kind of soil and is particularly suitable for light soils, late districts, and exposed situations.

RIVETT.—The well known bearded or cone wheat. Should be sown as early as possible. Chiefly grown on clay soils. Being awned, this wheat is to a large extent "sparrow proof" and will be found a useful variety to sow where birds are likely to do damage to ripening crops.

BROWICK.—Ears compact ; chaff white ; grain red ; straw medium length and stands well. This wheat does particularly well on good loam soils.

OFFICIAL NOTICES AND CIRCULARS.

N.B.—The Orders which may be mentioned in this section of the JOURNAL may usually be obtained at the price of 1d. each from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, and 28, Abingdon Street, London, S.W. 1 ; 37, Peter Street, Manchester ; and 1, St. Andrew's Crescent, Cardiff.

THE following Order (No. 1047), dated 10th August, 1918, has been made by the Board of Agriculture and Fisheries under Regulation 2M of the Defence of the Realm Regulations :—

The Cultivation of Lands Order, 1918 (No. 2).

Whereas under Regulation 2M of the Defence of the Realm Regulations (which so far as the same is applicable to England and Wales is set out at the foot of this Order), the Board of Agriculture and Fisheries (hereinafter referred to as "the Board") are empowered, after such consultation with the Food Controller as may be arranged, to exercise certain powers with a view to maintaining the food supply of the country, and to authorise any person, or any body constituted by the Board for the purpose, to exercise on behalf of the Board the powers conferred on the Board by Regulation 2M, and to prescribe the procedure of any such body and the authentication of any notice or other instrument issued by any body or person so authorised.

And whereas the Board, after consultation with the Food Controller, are of opinion that for the purpose aforesaid such Order as is herein contained should be made.

Now the Board of Agriculture and Fisheries do hereby order as follows :—

1. The persons who are for the time being appointed by a county council of an administrative county to act as members of the War Agricultural Committee for the county are hereby re-constituted as the body to exercise in manner herein provided such of the powers conferred on the Board by Regulation 2M as are hereby authorised to be so exercised.

2. The body hereby re-constituted shall maintain an executive committee consisting (1) of members appointed by the said body, not less than four nor more than seven in number, unless the Board otherwise direct, and (2) of additional members appointed by the Board. In the case of a county in Wales (including Monmouthshire), two of the members so appointed by the body hereby re-constituted shall be the members representing the council of the county on the Welsh Agricultural Council. If any vacancy occurs among those members of an executive committee who are appointed by the body hereby re-constituted, the executive committee may appoint any person to fill the vacancy so arising.

3. (1) The body hereby re-constituted for a county, acting through the executive committee, may on behalf and at the expense of the Board, but subject to such directions as to approval of expenditure or otherwise as may from time to time be given by the Board, and subject also to the restrictions imposed by this section, exercise within the county any of the powers of the Board under Regulation 2M (except the powers conferred by paragraphs (eee), (f), (h), (l), (m), (n) and (o) of Section (1) of that Regulation) and appoint such officers and incur such expenses as the committee may consider necessary or expedient for such purposes ; provided always that

- (a) The committee shall not enter on or take possession of any common land as defined by this Order, or take possession of any inhabited dwelling-house, without a further consent given by the Board ; and
- (b) Where any notice is served under the powers contained in paragraph (i) of section (1) of the Regulation such notice shall contain a provision to the following effect :—

This notice shall take effect at the expiration of seven days from the date of service hereof, unless before such expiration notice of appeal to the Board of Agriculture and Fisheries is given in writing to the Secretary to the War Agricultural Executive Committee, and in the event of any such appeal this notice shall take effect on such date (if any) as the Board shall determine after considering the appeal.

(2) The rights of any person dealing with the committee shall not be affected by any question as to compliance by the committee with any directions so given by the Board to the committee, or the requirement of consent in the case of common land or an inhabited dwelling-house.

4. (1) The Corn Production (Amendment) Act, 1918, provides that any person who on or after the 21st August, 1918, is under the powers of the Defence of the Realm Regulations exercisable by the Board with a view to maintaining the food supply of the country with respect to matters dealt with in Part IV. of the Corn Production Act, 1917, served with a notice which requires any change in the mode of cultivating or in the use of land in his occupation and is not solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry may within the time prescribed by the Board require a reference to arbitration of the question whether it is undesirable in the interest of food production that the change should apply to any portion of the land included in the notice. A copy of any such notice served on a tenant is at the same time to be served on the landlord.

Every such notice shall contain the notification of a right to appeal referred to in paragraph (4) of this section.

(2) The Act of 1918 also provides that before possession is taken under the said powers on or after the 21st August, 1918, for the purpose of securing any change in the mode of cultivating or in the use of land other than the conversion of the land into gardens or allotments, notice of intention to take such possession shall be served on the owner and occupier of the land if they can reasonably be ascertained, unless the notice is served solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry, and that an owner or occupier so served shall have the same right of reference to arbitration as is set out in the preceding paragraph of this section.

Except where possession is taken for the purpose of converting the land into gardens or allotments or solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry, a notice is required to be thus served, and every such notice shall contain the notification of a right to appeal referred to in paragraph (4) of this section.

(3) Where possession is taken by the Committee of any land for conversion into gardens or allotments or solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry, the Committee shall on or before the taking of possession give notice in writing to the owner and the occupier of the land if they can reasonably be ascertained, of the purpose for which possession has been or is to be taken.

(4) Except in the case of a notice to which the last preceding paragraph of this section relates, any notice to which this section relates which is served under this Order on or after the 21st August, 1918, shall contain a provision to the following effect :—

The occupier or owner of the land to which this notice relates is entitled by notice given to the Secretary of the War Agricultural Executive Committee within fourteen days from the date of the service of this notice on him to require the reference to arbitration of the question whether it is undesirable in the interest of food production that the change in the mode of cultivating or in the use of the land required by this notice should apply to any portion of the land.

5. An executive committee shall from time to time report their proceedings to the body re-constituted by this Order for the county, but the acts of the committee shall not be subject to confirmation by that body.

6. A member of an executive committee shall not take part in any decision of the committee which relates to land of which he is the owner or occupier, or the agent of the owner or occupier, or enter into any contract with the committee, unless such contract has been approved by the Board.

7. Accounts shall be kept by an executive committee of their receipts and expenditure and be open to inspection by any officer of the Board and those accounts shall be made up and audited in such manner as the Board shall direct.

8. An executive committee shall appoint a chairman of the committee. At any meeting at which the chairman is not present a person appointed by the meeting shall be entitled to act as chairman of the committee. At any meeting of an executive committee the chairman shall, in case of an equal division of votes have a second or casting vote.

9. The quorum, proceedings and place of meeting of an executive committee shall be such as the committee determine.

10. The proceedings of an executive committee shall not be invalidated by any vacancy among its members, or by any defect in the appointment or qualification of any of its members.

11. Minutes of the proceedings of an executive committee shall be kept in a book provided for that purpose, and a minute of those proceedings signed at the same or the next ensuing meeting by a person describing himself as, or appearing to be, chairman of the meeting at which the minute is signed shall be received in evidence without further proof.

12. Any notice, direction or other instrument signed by a person describing himself as, or appearing to be, chairman of an executive committee shall be received in evidence without further proof as a notice, direction or instrument issued by the executive committee.

13. Until the contrary is proved an executive committee shall be deemed to have been duly constituted.

14. An executive committee may, subject to any directions given by the Board, appoint such sub-committees as the committee thinks fit. A sub-committee may consist either wholly or partly of persons not being members of the executive committee.

15. An executive committee may act on behalf of the Board in any arbitration under the Corn Production (Amendment) Act, 1918, whether relating to compensation or any other matter.

16. In this Order, the expression "common land" includes any land subject to be enclosed under the Inclosure Acts, 1845 to 1882, and any town or village green and any other land subject to any right of common.

17. The Cultivation of Lands Order, 1918, is hereby revoked, but so that such revocation shall not affect the previous operation of such Order or anything done under it, or affect any right or liability acquired or incurred under such Order and any reference in any document to the Order hereby revoked or to any body constituted by any such Order shall be considered as a reference to this Order or to the body reconstituted by this Order.

18. This Order applies only to administrative counties in England and Wales.

19. This Order may be cited as the Cultivation of Lands Order, 1918 (No. 2).

In witness whereof the Board have hereunto set their Official Seal this nineteenth day of August, nineteen hundred and eighteen.

(L.S.)

T. H. MIDDLETON,
Assistant Secretary.

REGULATION 2M SO FAR AS THE SAME IS APPLICABLE TO ENGLAND OR WALES.

[NOTE.—Those paragraphs containing powers which are not delegated to Agricultural Executive Committee are indicated by a black line in the margin.]

"2M. (1) Where the Board of Agriculture and Fisheries, after such consultation with the Food Controller as may be arranged, are of opinion that, with a view to maintaining the food supply of the country, it is expedient that they should exercise the powers given to them under this regulation, the Board may—

" (a) Enter on and take possession of any land which in their opinion is not being so cultivated as to increase, as far as practicable, the food supply of the country, and, after entry thereon, do all things necessary or desirable for the cultivation of the land or for adapting it for cultivation ; and for such purposes enter on and take possession of any buildings on the land or convenient for such purposes ; and

" (b) Take possession of any machinery, implements of husbandry or plant (other than machirery, implements or plant in the possession or under the control of a dealer or manufacturer), or any farm produce, stock, or animals, which, in the opinion of the Board, are required for the cultivation of land or the increase of the food supply of the country ; and

" (c) Provide accommodation for persons, machinery, implements of husbandry or plant, farm produce, stock or animals, employed or used by the Board for the cultivation of land or the increase of the food supply of the country, by taking or retaining possession of any land or buildings ; and

" (d) Utilise any water supply or motive power for any such purposes ; and

" (e) By notice served on the occupier of any land require him to cultivate the land in accordance with such requirements as the Board may think necessary or desirable for maintaining the food supply of the country and may prescribe in the notice ; and

" (ee) By notice served on the occupier of any land require him in accordance with the terms of the notice to adapt the land for cultivation by repairing or removing any hedge or fence on the land, or by clearing or repairing any ditch or drain, whether natural or artificial, by which the land is capable of being drained ; and

" (eee) By order, applicable generally or to any specified area, and published in such manner as the Board may consider to be best adapted for informing persons thereby affected, prohibit or regulate the use of land for the cultivation of any crop specified in the order and by any such order require the ploughing up within such time as may be specified in the order of any land in use at the date thereof for the cultivation of any such crop ; and

" (f) By notice served on the tenant of any land which or part of which, in the opinion of the Board, is not being so cultivated as to increase as far as practicable the food supply of the country, determine his tenancy of the land on such date as may be specified in the notice, or, on the application of the landlord by order authorise him in any such case to determine the tenancy in accordance with the terms of the order ; and

" (g) After entry on any land arrange for its cultivation by any other person whether by contract or tenancy or otherwise ; and

" (h) Where, in the opinion of the Board, any land is injured or is likely to be injured by any such neglect on the part of the proprietor or occupier of any other land in relation to the maintenance of banks or the cleansing of channels as is mentioned in section 14 of the Land Drainage Act, 1847, and subject to, and after the expiration of 7 days from, the service of such notice as is required by that section, exercise such powers of executing all necessary works and recovering the expenses thereof as are by that

section conferred on the proprietor or occupier of any land which is injured by any such neglect, and for any such purpose to enter on any land without any warrant or authority ; and

“(i) By notice served on the occupier or person in control of any dam, mill, lock, sluice, weir, or other structure affecting the flow of water in any river or stream require such occupier or person to keep open or closed any mechanical appliance by which the inflow or outflow of water is capable of being regulated during such times and in such manner as the Board, having regard to the use by such occupier or person of the structure and of the water thereby impounded, consider to be necessary or desirable for the prevention of floods or for the draining of land adjoining or near the river or stream ; and

“(j) Where, in the opinion of the Board, any land is injured or likely to be injured by flooding or inadequate drainage which might be remedied wholly or partially by the exercise of powers which are conferred by any general or local Act, or by an award made under any Act, or by any Commission of Sewers, and which are not being exercised, or in the opinion of the Board are being insufficiently exercised, exercise any such power and also any power conferred by any such Act or award or commission for defraying the expenses so incurred or for any purpose incidental to the exercise of any such power ; and

“(k) Enter on or take possession of any dam, mill, lock, sluice, weir, or other structure affecting the flow of water in any river or stream, and remove or repair or alter or maintain and use the same where such action is in the opinion of the Board necessary or desirable for the prevention of floods or for the drainage of agricultural land ; and

“(l) For the purpose of removing any obstruction to or otherwise improving the flow of water in any river or stream, or maintaining or improving the banks of any river or stream or any sea defence or drainage outfall, enter on the river or stream or any land adjoining or near the river, stream, defence, or outfall ; and

“(m) Where any expenses are incurred by the Board in the exercise of any of their powers under paragraphs (k) or (l) of this regulation, recover those expenses, so far as they are directly attributable to the default of any person in carrying out his obligations under statute or otherwise, from that person ; and

“(n) On the application of any drainage authority empowered by a local Act to levy rates to a limited amount, by order increase the amount that may be so levied ; and

“(o) By notice served on the occupier of any agricultural land or the person having the management of any such land require him to make within such time and in such form and to such person as the notice may prescribe a return in writing with respect to the cultivation of the land or the crops or live-stock thereon or any other matter as to which the Board may desire information for the purpose of the proper exercise of their powers under this regulation, but so that no such return or any part thereof shall be published or disclosed except for the purposes of a prosecution under this regulation.

" (2) An occupier of land may, with a view to maintaining the food supply of the country, submit to the Board a scheme for the cultivation of the land in a manner not consistent with the contract of tenancy of the land, and the Board, if satisfied that the adoption of the scheme is necessary or desirable for the maintenance of the food supply, may direct that the land shall be cultivated in accordance with the scheme, subject to any modification which the Board may think fit to make therein.

" (3) If any person obstructs or otherwise interferes with or impedes any officer in the execution of his powers under this regulation, or discloses or publishes any return or part thereof in contravention of this regulation, or negligently or wilfully fails to comply with the requirements of any order made under this regulation, or with any condition subject to which a licence under any such order has been granted, or, being an occupier of any land or building of which the Board require possession, or of which the tenancy of the occupier has been determined by notice served under this regulation, without lawful excuse, refuses to give possession thereof to the Board or to quit such land or building, or, having been served with a notice under this regulation requiring him to do any act, negligently or wilfully fails to comply with the requirements of the notice, or, where the notice requires him to make a return, makes a false return, he shall be guilty of a summary offence against these regulations.

" (4) If the Board at any time withdraw from possession of any land of which possession has been taken under this regulation, they may recover from any person then interested in the land as owner or tenant or otherwise, such amount as represents the value to him of all acts of cultivation or adaptation for cultivation executed by the Board ; such amount to be determined, in default of agreement by a single arbitrator under and in accordance with the provisions of the Second Schedule to the Agricultural Holdings Act, 1908.

" (5) Any person authorised by the Board in that behalf may, for the purposes of this regulation and upon production if so required of his authority, enter on and inspect any land or building and inspect any machinery, implements of husbandry, farm stock or produce thereon.

" (6) The Board may with respect to any land or land in any district authorise any person or any body constituted by the Board for the purpose to exercise on behalf of the Board any of the powers of the Board under this regulation and prescribe the procedure of any such body, and the authentication of any notice or other instrument issued by any body or person so authorised.

" (7) The powers conferred on the Board by this regulation shall be in addition to and not in derogation of any other powers of the Board.

" (8) In this regulation the expression 'cultivation' includes use for grazing and the expression 'cultivate' has a corresponding meaning.

" (11) Any notice under this Regulation may be served on the person to whom it is to be given either personally or by leaving it for him at his last known place of abode or by sending it through the post in a registered letter addressed to him there."

THE following Letter (No. C.L. 73/C. 1), with enclosure, was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 15th August :—

**The Food Production
Programme for 1919
and the Corn Produc-
tion (Amendment)
Act, 1918.**

SIR,—I. The Corn Production (Amendment) Act, 1918, which comes into operation on the 21st inst, modifies in certain important respects the powers of the Board and of the Agricultural Executive Committees under the Defence of the Realm Regulations. A Memorandum explaining the effect of the Act is enclosed* for the information of your Committee, which should be carefully studied in order that the necessary changes in procedure should be adopted. The Memorandum is being printed and copies will be sent to you in due course for distribution.

2. In the Circular Letter of the 15th ult., certain interim instructions were given with regard to the programme for the harvest of 1919 and the Department are now in a position to inform Committees in greater detail of the nature of the work which they are asked to undertake.

3. The recent decision to withdraw 30,000 men from the land for the Army made it necessary to reconsider the plans which the Department had prepared for the harvest of 1919, but the urgent need of increased production remains unaffected. In dealing with agriculture long views are essential, and the fact that the supply of food at the moment is somewhat more satisfactory does not justify any relaxation of the efforts of the Committee. Whether the War ends soon or late, increased production at home is a matter of vital importance. The declaration of peace may even accentuate the need, as the Central Powers will then compete with us for food supplies in the exporting markets of the world. Moreover, on grounds of finance it is imperative to reduce our foreign indebtedness as much as possible, and, in view of the continued serious situation in regard to shipping, and the increasing demands on tonnage for the use of the American Army, it is increasingly clear that our only sure hope of security during the War and of recovery afterwards is to render ourselves as nearly as possible self-supporting in regard to all essential foodstuffs. It is the duty, therefore, of the Department and of the Committees to look forward not only to the harvest of 1919, but to 1920, and subsequent years, and to lay our plans so that a forward movement may be undertaken rapidly, as the supply of labour improves.

4. The efforts of the Committees should largely be directed to improving the cultivation of the remaining grass area, and of the existing arable land, including that which has been broken up during the past 18 months, in order to secure from both the maximum possible production of food. The staff of the Committee has now been strengthened and reorganised; public opinion has been converted to the tillage policy; the prejudice against unaccustomed forms of labour has been broken down; the women, the soldiers, and the prisoners have proved their capacity; and the use of mechanical aid has been greatly extended and its efficiency improved. The Committees are therefore in a position to help farmers in many directions, and they should develop this side of their work as much as possible. At the same time they should use their powers to raise the general standard of all

* See below.

farming to the level of the best in the county. It is generally recognised that there is room for great improvement in the manner in which many farms are cultivated, and the Committees should pay special attention to negligent and indifferent farmers by helping them with advice and assistance, and, if these means fail, by using the powers of the Committees to secure such cultivation as is necessary in the national interest. Under present conditions wilful failure to make the best use of land in the interest of the Nation cannot be tolerated, and the Department are sure that Committees will not hesitate to take whatever measures are required to deal with such cases. In doing so they will have behind them the best public opinion of the whole community. By proceeding on these lines there is no reason why the production of food in 1919, from land already under the plough, should not be increased.

5. In order to make a substantial increase in 1919 on the output of corn in 1918 the Department intended to aim at adding about another 1,000,000 acres, to the arable area, of which the quota provisionally allotted to your county was — — acres. The shortage of skilled labour has rendered it impracticable to break up where such labour is really found to be deficient, but the Department are most anxious that Committees should keep this ideal in view and should encourage farmers to plough up and cultivate as arable more grass land wherever they have the strength to do so without neglecting their existing arable land.

6. It is not intended, therefore, that Committees should abstain from issuing any notices requiring grass land to be broken. Such notices should be issued in all cases where the owner and occupier agree, in order that their right to claim compensation in case of loss may be safeguarded. Notices should also be served in all other cases in which the Committee are satisfied, after careful inquiry, that the land can be put to its best productive use by growing corn or potatoes, and that the occupier has or can obtain sufficient labour to plough up the land and keep it in cultivation in addition to his existing arable land. Such notices can be referred to arbitration if the owner or occupier objects, and Committees should therefore take special pains to satisfy themselves on the points mentioned above before issuing any notice, so that if the matter goes to arbitration the Committee will have a good case in support of the notice. The governing consideration should always be whether or not it is in the best interests of increased food production that the land should be ploughed up.

(Signed) R. E. PROTHERO,

President of the Board of Agriculture.

(Signed) CHARLES FIELDING,

Director-General of Food Production.

ENCLOSURE.

1. The Corn Production (Amendment) Act, 1918, keeps in operation, with some important modifications, the powers of the Board and of the Agricultural Executive Committees under the Defence of the Realm Regulations which would otherwise have ceased to be exercisable on the 21st August, 1918.

2. A new Cultivation of Lands Order adapted to these modifications is in preparation and will be issued shortly,* but in the meantime it is

* See p. 718.

desirable that Committees should be informed at once of the changes in procedure required by the Act. These changes fall under two main heads which will be dealt with separately.

A.—APPEALS TO ARBITRATION.

3. In the first place, the Act provides that the exercise of certain of the powers of the Board under the Defence of the Realm Regulations shall be subject to a statutory right on the part of the owner and the occupier of the land to have the matter referred to arbitration before the powers can be enforced. In such cases the arbitration will be before a single arbitrator under, and in accordance with, the provisions of the Second Schedule to the Agricultural Holdings Act, 1908, except that the arbitrator will be appointed, in default of agreement, by the President of the Surveyors' Institution.

4. The cases in which there will be a right to require a reference to arbitration fall under three heads, which are dealt with separately below ; but Committees should understand that, with those exceptions, their powers remain unaltered, and that in regard to many branches of their work their operations can continue on the same lines as have hitherto been adopted. Even in those cases which are subject to appeal and arbitration there is no reason to fear that appeals will be numerous if the Committees exercise due care and judgment before issuing notices, and the fact that costs may be awarded against an appellant will discourage frivolous appeals.

(I.) Determination of Tenancies.—5. This power remains in the hands of the Board and is not delegated to Agricultural Executive Committees, but Committees may recommend to the Board that it should be exercised in the case of negligent or indifferent farmers whose land is not properly cultivated and where efforts have been made by the Committee without success to secure proper cultivation. No recommendation for the determination of a tenancy should be made unless the Committee have satisfied themselves by personal inspection on their behalf that it is essential in the national interest, and as a general rule the occupier should in the first instance be given an opportunity of carrying out such acts of cultivation as in the opinion of the Committee are necessary to secure that his land is cultivated according to the rules of good husbandry.

6. On receipt of a recommendation that a tenancy should be determined, the Board, if they are satisfied that the recommendation should be adopted, will issue a notice determining the tenancy. The notice will be served by the Committee on the occupier and a copy sent to the owner, and either of them can require that the question whether the land has been cultivated according to the rules of good husbandry shall be referred to arbitration. Pending the decision of the arbitrator the operation of the notice will be suspended.

(II.) Notices requiring any Change in the Mode of Cultivating or in the Use of any Land.—7. The notices in this class will include those requiring grass land to be ploughed up and cultivated as arable, but not notices which are solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry. What are known, therefore, as "ploughing orders" will be subject to appeal and reference to arbitration, but not ordinary "cultivation orders." In the case of "ploughing orders" or any other notices served on or after the 21st August, requiring any change in the mode of cultivating

or in the use of any land (such, for instance, as a notice requiring an occupier to plough up a strawberry bed and to use the land for some other crop), the notice should be served on the occupier by registered post and a copy served at the same time on the owner also by registered post. If either of them within 14 days from the service of the notice requires that the matter shall be referred to arbitration, the Committee should submit to the appellant the name or names of one or more persons whom the Committee would agree to accept as arbitrator. If within (say) 10 days the appellant does not agree to the appointment of one of the persons suggested by the Committee, the Committee should apply to the President of the Surveyors' Institution, 12, Great George Street, S.W. 1., to appoint the arbitrator. It will be open, however, to the Committee or to the appellant to apply forthwith to the President of the Surveyors' Institution to appoint the arbitrator without first submitting names for consideration. When the arbitrator has been appointed he will proceed with the reference in accordance with the practice under the Agricultural Holdings Act, and it will be within his discretion to award how and by whom the cost of the arbitration shall be paid.

8. In view of the uncertainty as to when a notice can be enforced in consequence of the possibility of a reference to arbitration, and of the desirability of a definite date being fixed for the completion of any work required by the notice, so as to establish default in case proceedings have to be taken, it would be desirable, where this would meet the necessity of the case, to specify in the notice a date for the completion of the work required which is not less than three months from the date of service of the notice. Where this is undesirable the notice should require the work to be done within a specified period after the expiration of the 14 days allowed for an appeal, or where an appeal is lodged, after the arbitrator issues his award.

(III.) Taking Possession of Land.—9. It is important that Committees should understand clearly the position under this head. Their power of taking possession of land under Paragraph (1) (a) of Regulation 2M remains unaltered if the land is to be converted into gardens or allotments or if possession is to be taken solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry. In those cases there is no statutory requirement that notice of the Committee's intention shall be served on the owner or occupier before possession is taken and the owner or occupier has no right to have the question referred to arbitration; but it is desirable that the owner and occupier should know that possession is being taken, and accordingly provision is being made in the new Order requiring such notification to the owner and occupier if they can reasonably be ascertained, but such notification does not give any right of appeal to an arbitrator. If, however, the Committee propose to take possession of any land for the purpose of securing any other change in the mode of cultivating or in the use of the land, notice of their intention must under the new Act be served on the owner and occupier if they can reasonably be ascertained, and either of them can require the reference to arbitration of the question whether it is undesirable in the interest of food production that the proposed change should apply to any portion of the land, and the procedure will be the same as that described under the preceding heading. It is probable that occasions will not often arise when Committees desire to take

possession of land, except for the provision of gardens or allotments, or for the purpose of securing that the land shall be cultivated according to the rules of good husbandry. If, however, a Committee desire to take possession of grass land for the purpose of ploughing it up, they will have to serve notice of their intention before doing so and the notice would give the owner and the occupier the right to have the proposal referred to arbitration.

B.—COMPENSATION.

10. The other principal change which is made by the Corn Production (Amendment) Act is in regard to compensation. Except as regards cases in which the Defence of the Realm (Losses) Commission have already determined the amount of any compensation payable or the compensation is agreed, all claims for compensation in respect of loss suffered by reason of the exercise of those powers of the Board under the Defence of the Realm Regulations, which are continued in operation by the Act, will in future be settled by arbitration instead of by the Losses Commission. This provision is retrospective and will apply to claims made in consequence of action taken before as well as after the passing of the Act. Instructions on this matter will be given in a separate Memorandum which will be issued shortly.*

THE following Memorandum (No. C.L. 75/C.1) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 23rd August :—

Claims for Compensation.

1. Withdrawal of Claims for Compensation from the Losses Commission.—The Corn Production (Amendment) Act, 1918, provides as follows :—

(c) "Where before or after the passing of this Act any notice has been or shall be served, order made, or possession of land taken under the powers continued in operation by this sub-section, the provisions of this part of this Act relating to the determination and recovery of compensation shall apply as if the notice had been served, the order made, or possession taken under the powers conferred by Section 9 of this Act, except in any case in which the compensation has been otherwise determined."

Accordingly, claims for loss on account of action to which the above proviso refers will no longer be brought before the Defence of the Realm (Losses) Commission.

This change does not apply to claims for every kind of loss that may be occasioned by action under Regulation 2M, but only for loss due to action "under the powers continued in operation by this sub-section," and the effect of this limitation is explained in paragraph 7 below.

2. Procedure now Applied to such Claims.—Under the Corn Production Act, 1917, Section 9 (9), which is thus applied, any person interested in land in respect of which a notice has been served or an order has been made, or of which possession has been taken under any of the powers of Regulation 2 M continued in operation, who has suffered loss by the exercise of such powers is entitled to be paid by the Board such amount as represents the loss; and the amount may take the form of periodical payment, e.g., for loss of rent.

* See below.

The Statute provides that if the Board prescribe a period for making claims, the claim must be made within that period ; but at present the Board are not prescribing any period within which the claims must be made.

It is hoped that in the majority of cases the Department may be able to agree with the claimant the amount due.

Failing agreement, the amount payable is to be determined by a single arbitrator. The arbitrator may be nominated in writing by agreement between the Committee and the claimant ; if they cannot agree on the nomination, the arbitrator will be appointed by the President of the Surveyors' Institution on the application in writing of either the Committee or the claimant.

The arbitration will be conducted under and in accordance with the Second Schedule to the Agricultural Holdings Act, 1908.

3. Mode of Making Claims.—Claims for loss affected by the new Act will continue to be made through Agricultural Executive Committees. When it is desired that the claim should be dealt with forthwith it should be made in duplicate on the form F.P. 352/C1, a specimen of which is annexed to this Circular.* On receipt of such a claim in duplicate one copy should be sent by the Agricultural Executive Committee to this Department and the other retained by the Agricultural Executive Committee for report. A report should be prepared by a surveyor appointed by the Agricultural Executive Committee for the purpose or by a qualified official of the Committee as heretofore according to the specimen Form (F.P. 124), which is already in use, and should be sent to the Department as soon as possible, together with the observations of the Committee on the claim. This report should be kept confidential, and its contents should not be disclosed to the claimant. The second copy of the claim should not be forwarded, but should be kept by the Agricultural Executive Committee for filing.

It is undesirable that the Executive Committee should make any attempt to enter into provisional agreements for the settlement of claims.

Where the claimant makes a claim for matters such as are dealt with in a tenant right valuation, and states that he proposes to make a further claim for any other matter (except reinstatement) the application should be returned to him with a suggestion that he should apply in a single application in respect of all the items for which he proposes to claim, in order that the Department may have the whole case before them at one time. As pointed out above, periodical payments may be made ; and, consequently, the making of a complete claim at the present time will not prejudice the applicant in continuing to obtain any compensation that may be awarded to him for loss of rent and similar matters up to the time when the Committee withdraw from possession.

A copy of the tenancy agreement or leases should be sent to the Department in each case in which such a document exists.

4. Dilapidations.—Land of which possession is taken or of which a tenancy is determined is often in such a state that a claim would lie by a landlord against a tenant for dilapidations as regards the cultivation and also as regards the farmhouse, buildings, hedges, and ditches. In reporting on such a case the surveyor employed by the

* Not here printed.

Executive Committee should include in his report a Schedule of dilapidations, giving the price of each item, and a copy of this Schedule should be furnished to the applicant. The same remarks on this point apply where the land is in the occupation of the owner at the time of taking possession as where it is in the occupation of a tenant. In either case the Department consider that information as to the sum required to put the land into a proper state of cultivation and the buildings into repair may be of use in reducing the amounts that would otherwise be payable in respect of claims for loss occasioned by the taking of possession or the determination of a tenancy.

5. Claims on Breaking up of Grass Land.—It has been found in the majority of cases in which grass land has been broken up in consequence of a notice served under Regulation 2M that the amount of any loss in value of the land cannot be ascertained at the present time. Where the landlord or tenant who claims to have suffered loss is of this opinion, and is content that his claim should stand over with liberty to apply at any time for a settlement, he should send in a notice of his intention to claim on the Form F.P. 353/C.1, a specimen of which is annexed hereto,* which should be sent in duplicate. One copy should be forwarded to the Department with a copy of the notice requiring the land to be broken up, and a record of the character and condition of the grass land before breaking up (including, where possible, a statement of the annual value of the land before breaking up). Where a notice of intention to claim is received, such a record should be made forthwith. The second copy of the notice should be retained by the Agricultural Executive Committee for filing.

6. Claims in respect of Loss arising by the Failure of Crops on Land Ploughed up under a Cultivation Order.—When claims or notice of intention to claim are received by Committees for loss of this nature, an inspection and report should be made without delay. The report should give the area of the holding and the proportion of arable and pasture which it comprises. If the Cultivation Order was not specific as to the land to be broken up, or as to the crop to be planted, but left the choice to the occupier, it should be stated whether the land on the farm best suited for the purpose was chosen and whether the crop most likely to succeed was planted. The report should also state whether the crop is a total failure, and if not, the value of the portion that has been, or is likely to be, harvested. The cause of the failure must be stated and special enquiry made as to whether any negligence of the applicant in cultivation or sowing has contributed to the failure, and to what extent. It should be stated whether the requirements of the Cultivation Order are considered to have been reasonable and whether the land is likely to be profitable in subsequent years under arable culture. Each item of the claim should be reported on and a statement furnished as to whether the applicant's entire expenditure, or if not, how much of it, is likely to be unproductive.

7. Claims for Loss other than that Above Referred to.—The provision of the Corn Production (Amendment) Act, 1918, above set out, does not cover the whole ground of Regulation 2M, but only powers exercisable with respect to matters dealt with in Part IV. of the Corn Production Act, 1917. Those matters are the requirement of occupiers and owners to cultivate according to the rules of good husbandry or to

* Not here printed.

change the mode of cultivating any land or the use to which it is put, and in connection therewith the termination of tenancies and the entry on land and its cultivation by the Board. From this it will be seen that claims for compensation for loss occasioned by the exercise of some of the powers under Regulation 2M still fall within the jurisdiction of the Defence of the Realm (Losses) Commission. The principal of these are claims for loss of the value of live and dead stock of which possession has been taken under Paragraph 1 (b) and for loss of rent of land or buildings taken for the accommodation of labour or stock, employed or used by the Board, under Paragraph 1 (c). It will be inconvenient for the Commission to have to adjudicate on a part only of the items commonly included in an outgoing valuation, *i.e.*, the stock, implements, etc.; and it will consequently be advisable, wherever this can be arranged, for the Agricultural Executive Committee to buy these of the dispossessed occupier rather than to take possession of these under the compulsory powers of Regulation 2M. The price at which it is proposed to buy these should be reported to the Department before being agreed.

With regard to the occupation of land and buildings used for camps and stables, the Department hope to obtain power to pay agreed rent and a further communication will be sent.

8. Previous Instructions.—All previous instructions issued by the Department on the preparation and forwarding of claims for compensation are hereby cancelled, with the exception of the Specimen Form of Report, F.P. 124, referred to above.

List of Circulars and Memoranda cancelled :—

9. Pending Claims.—Any applications to the Losses Commission for compensation that are pending with Agricultural Executive Committees for report should be treated as in the past, and as soon as the report is completed it should be sent forward to this Department with the claim. The Department will deal with the claim on receipt of the report.

Any claims now received on the forms issued by the Losses Commission should be similarly dealt with, but a duplicate of the application need not be sent to the Commission. Applicants who have sent in such forms need not be asked to submit their claims in the new forms.

The Department are in communication with the Commission as to the disposal of cases already pending with them.

THE following Notice was issued by the Food Production Department of the Board on 30th August :—

Reports continue to reach the Food Committee Farming. Production Department showing excellent results obtained by county committees that have taken over farms in a bad condition of cultivation and have managed them during the past year or two. An instance may be mentioned from Norfolk, where the Committee in February, 1917, entered upon a farm of 350 acres, most of it in outrun leys or derelict, only 12 acres being ploughed. The farm is managed by the Executive Officer of the county, with the assistance of a bailiff. Fifty-five acres remain in permanent grass. The cropping this year is : wheat, 85 acres ; barley, 39 acres ; oats, 70 acres ; roots, 59 acres ; other crops, 41 acres. Crops are looking well and there is little doubt that the financial results of the Committee's occupation will be most satisfactory.

In another case a farm practically derelict was taken over last year, when only 50 acres out of a total of 420 were ploughed. At present there are over 400 acres under food crops—111 acres of wheat, 83 acres of barley, and 57 acres of oats. All the crops look well, and, as an official report says : "The marked general improvement effected in so comparatively short a time is an excellent illustration of the national importance and value of efficient farm management."

THE following Memorandum (No. C.L. 74/C.1) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 21st August :—

Credit for Farmers. It has been represented to the Department that there are numerous cases in which it is desirable to provide a farmer with additional working capital in order to enable him to pay promptly for cultivations undertaken by the Agricultural Executive Committee. The Department have been in communication with the Treasury on the subject, and have now obtained authority for such cases to be dealt with under the Credit Scheme ; that is to say, an occupier for whom cultivations are carried out by the Committee, but who has not sufficient ready money to pay cash for those cultivations, may apply to the Committee for the grant of credit, and thus obtain an advance from his bankers to enable him to settle the Committee's account.

This concession should be of distinct advantage in those cases where an occupier who is short of working capital breaks up additional land, thereby undertaking increased financial responsibility ; and it will obviate action under Regulation 2M (1) (a) in many cases where it would otherwise be necessary for the Committee to enter and take possession, with a view to carrying out the cultivations and recovering the cost when the crops are harvested.

In acting on the authority now given, Executive Committees should exercise the greatest care to ensure that credit is only allowed to suitable applicants, who may be expected with the measure of assistance thus afforded to them to carry on the subsequent work of cultivation to a satisfactory conclusion.

THE following Circular Letter (No. C.L. 43/H.) was addressed to Horticultural Sub-Committees by the Food Production Department of the Board on 22nd August :—

**Agricultural
Organisation Society
and Food Production.**

SIR,—I am directed to inform you that the Agricultural Organisation Society is prepared to render assistance to this Department in the work of food production. The Society is prepared to assist the Horticultural Sub-Committees in providing allotment societies and similar organisations with information and assistance with respect to business methods, the principles of co-operation and the practice of co-operation in the purchase of horticultural requirements and owning of tools, implements, etc.

The Agricultural Organisation Society is also prepared on receipt of a request from this Department to assist counties with respect to Marketing Organisations in their counties. The Department are anxious that use should be made of the Agricultural Organisation Society in these directions, but, at the same time desire to point out to Horticultural Sub-Committees the necessity for care being taken for preventing over-lapping and duplication of work.

The Department are asking the Society to forward for the information of the Sub-Committee a detailed memorandum of its programme of work in connection with the organisation of co-operation among small cultivators.

I am, etc.,

(Signed) G. F. MIDDLETON.

For Controller, Horticultural Division.

THE following Memorandum (Ref. C.L. 250/M.6) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 17th August :—

Labour on Tractors. It has become necessary owing to the issue of revised Regulations by the Army Council in regard to the pay of soldiers, and to the fixing of local rates by Agricultural Wages Boards, to cancel all previous instructions ; and the arrangements as to the employment of labour must in future conform to the terms of this Circular.

Payment to Existing and Future Competent Labour.—In each county where the Agricultural Wages Board have fixed rates, all soldier, civilian and women labour must be paid the minimum rate fixed for the number of weekly hours specified by such Board. This entails the abolition of the present 30s. rate and 60 hours per week in these counties.

Overtime in excess of the hours specified by the Board, and Sunday work, must be paid for at the rate fixed by such Board, and Sunday pay at the overtime rates, if no other rate has been fixed.

In addition a bonus not exceeding 8*d.* in the pound charged to the farmer in respect of any one tractor and implement may, at the discretion of the Committee, be paid to persons engaged on tractor work, *i.e.*, if the bonus were fixed at 3*d.* in the pound and the team consisted (a) of one person, the bonus payable would be 3*d.* in the pound, (b) of two persons, the total bonus payable would be 6*d.* in the pound, and (c) of three persons the total bonus payable would not exceed 8*d.* in the pound. In exercising this discretion Committees should bear in

mind the great importance of keeping their present labour as the responsibility for replacement now rests with them.

In the unlikely event of the above rates (including bonus) falling short of the minimum for soldiers, namely 12s. 6d. per week, plus board and lodging, soldiers must be paid such minimum.

If no Agricultural Wages Board rate has been fixed, the present scale will obtain until such rate is fixed, viz., 30s. per week, without overtime for a 60 hours week, plus bonus of 1s. an acre ploughed, etc., and 6d. per hour for Sunday work up to a maximum of 5s. for any day.

When a tractor is not working, every effort should be made to find other agricultural work for the labour either by hire to a farmer, to an engineer contractor, or by any other means at such rates as may be arranged by the Committee. The wages for such labour must be paid by the hirer direct to the employee, and the Committee should only pay the difference (if any) to make up such wages at the full Agricultural Wages Board minimum without bonus, or the 30s. per week as the case may be. When no such work is available, the minimum wage applicable must be paid in full.

It has not been found in practice that the training of men interferes with the output of the tractor, and in future the 10s. bonus paid for each man passed as competent will be cancelled.

Any person necessarily living more than one mile from his or her work may, at the discretion of the Committee, receive in the case of a bicycle, 1d. per mile for using it for travelling to and from work, or railway expenses not exceeding 3s. per week.

When necessarily living away from home married civilians and unmarried civilians whose homes are mainly dependent on them, may be paid a subsistence allowance of 17s. 6d. per week, and unmarried civilians whose homes are partially dependent on them, may be paid a subsistence allowance of 10s. 6d. per week. The Committee must make such enquiries as will satisfy them that the employee is entitled to the allowance, and must obtain a signed declaration from him or her to that effect. The Committee will pay the subsistence allowance to civilian tractor workers. Care must be taken that subsistence allowance is not paid twice over to men who are National Service or War Agricultural Volunteers.

Should it become necessary to dismiss labour owing to the shortage of work reference should first be made to the Department with a view to the surplus labour being transferred elsewhere. If this is not possible soldiers can then be returned to their agricultural companies; only as a last resort should civilian labour be dismissed, or women returned to county depots.

Individual applications by men or women for transfer to other counties in which they ordinarily reside will in future be arranged between the Committees of the counties concerned, but in the case of soldiers authority must be obtained from the Officer Commanding the men's Agricultural Company, and, in the case of women from the County Organising Secretary of the Women's Branch, before transfers are effected.

Learners.—Committees must make such provision for future labour as they may consider necessary, and unskilled persons engaged should be placed for tuition as second hands with Fordson tractors or third hands with other tractors. It is desirable that women undergoing tuition should be placed under the charge of other women who are

already competent and those Committees who do not at present employ women should apply to the Department for competent women before taking on learners.

Unskilled labour for training may be obtained by any of the following methods, which should be tried in the order laid down :—

- (a) Application to the Local War Pensions Committee for the services of discharged soldiers and sailors.
- (b) Application to the Local Employment Exchanges for War Agricultural Volunteers where all these are not enrolled by the Committee.
- (c) Application to the nearest agricultural company for soldiers.
- (d) Application to the Women's War Agricultural Committee.
- (e) Application to the Department.

Payment for civilian, women and soldier learners (except discharged soldiers and sailors) will be the Agricultural Wages Board minimum rate without bonus until considered competent. If no such minimum has been fixed the following rates should be paid, viz., 25s. a week for two weeks, 30s. a week for two weeks, and then when competent 30s. a week and acreage bonus.

Discharged soldiers and sailors will be paid by the Ministry of Pensions until such time as they are taken over by the Committee as competent tractor-driver ploughmen. All information regarding the terms of employment of such men should be obtained by the Committee from the Secretary of the Local War Pensions Committee.

Any learners (except discharged soldiers or sailors paid by the Ministry of Pensions) may be paid subsistence and travelling allowances on the same terms as competent labour.

Leave.—Leave to which soldiers are entitled is laid down in Army Regulations, and particulars may be obtained from the man's Commanding Officer. During leave they will receive Army pay from their agricultural companies, and they will not therefore receive any payment from the Committee during such absence.

Civilians and women may receive six days' leave after six months' work, and thereafter six days' leave every six months. They will receive no pay during such periods and will have to pay their own railway expenses unless Committees are notified to the contrary at any future date.

Leave should only be granted when, in the opinion of the Committee, the labour can reasonably be spared.

THE following Memorandum (No. C.L. 125/L. 2) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 16th August :—

Prisoners of War. It is necessary to amplify the instructions contained in paragraph 2 of the Memorandum of the 17th July * as to Women of the Land Army and prisoners of war not being allowed to work on the same farm :—

(a) It must be an invariable rule that women of the Land Army are not to be sent to farms where prisoners are boarded and lodged with the farmer under Scheme B. In the same way prisoners must not be sent to farms under Scheme B, if Land Army women are employed.

(b) In cases where a woman of the Land Army is employed by a farmer as a stock-woman or milker, etc., a Committee may allow the

* Printed in this *Journal*, August, 1918, p. 592.

farmer to have a gang of prisoners daily from a depot for work in the fields, provided that care is taken to ensure that the prisoners are employed on a different part of the farm from that where the Land Army woman is engaged.

(c) As regards gang labour of both types, it is always undesirable that gangs of Land Army women and gangs of prisoners should work on the same farm ; but where labour cannot otherwise be provided it may be permitted, provided that during the time the prisoners are on the land they are kept entirely apart from the women of the Land Army.

THE following Memorandum (No. C.L. 123/L.1) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 8th August :—

Stud Employees. In view of the importance attached by the War Office to the maintenance of the light horse breeding industry, the Department have been in communication with the Ministry of National Service with a view to stud employees generally, not merely stallion men and leaders, being certified on the authority of the Board of Agriculture and the Ministry of National Service under paragraph 9 of the Schedule to the Military Service (Agricultural Exemptions) Order, 1918, as being engaged in an occupation of national importance in connection with agriculture.

Pending a final decision in the matter, the Ministry of National Service have agreed that provisional vouchers may be issued by Agricultural Executive Committees in cases of urgency in order to retain the services of men who may be regarded as essential. In any cases of stud employees which come to the notice of Agricultural Executive Committees, provisional vouchers may be issued until further instructions have been received from the Department.

THE following Memorandum (No. C.L. 128/L.1) was addressed to Agricultural Executive Committees by the Food Production Department of the Board on 26th August :—

Agriculturists and the Volunteer Force. Representations have recently been made to this Department as to the position of agriculturists who are members of the Volunteer Force either by voluntary enlistment or by instructions from tribunals. Under the Agricultural Exemptions Order, 1918, Agricultural Executive Committees are now the authorities responsible for the exemption from military service of men engaged in agriculture and allied trades and the following information on the subject is, therefore, furnished for their guidance.

Agricultural Executive Committees have no power to release men from their obligation to attend drills in accordance with their agreements when joining the Volunteer Force, nor may they at present make it a condition, when issuing a voucher under the Order, that the holder must join the Volunteer Force.

As regards the release of agriculturists from the Volunteer Force, the Department have been in communication with the War Office, and it is agreed that in any case where it is impossible for a man to attend drills without serious interference with his civil work, the man should make representations to his Commanding Officer. Any application by an agriculturist for release from his Volunteer obligations should be

supported by the Agricultural Executive Committee, if they are satisfied that the application is genuine and that the man's work is adversely affected by his liability to drill. If put forward in this way an application for release will be carefully and sympathetically considered.

It is suggested that when representations are made by agriculturists to the Agricultural Executive Committees the above procedure should be adopted.

THE following Memorandum (No. C.L. 247(a)/M.3), was issued by the Food Production Department of the Board on 15th August :—

Repairs to Steam Ploughing and Threshing Tackle, Farm Vehicles, and Agricultural Machinery. in connection with the issue of priority certificates for the repair of steam ploughing and threshing tackle, farm vehicles and agricultural machinery :—

The actual owner must apply to the Agricultural Machinery Department, Ministry of Munitions, 8, Northumberland Avenue, London, W.C. 2, giving a detailed list of engines, machines, or vehicles in his possession, stating type and maker's name in each case. This list may include any of the following :—

- (a) Ploughing engines and tackle, threshing engines (not stationary), threshing machines and tackle, farm vehicles, reapers, binders, or mowing machines.
- (b) Any other vehicles or engines running on wheels, not exclusively used for farm purposes.

On receipt of this information, the Agricultural Machinery Department will ask the Priority Department to grant the owner a *running permit which will enable him to have any ordinary repairs done at any time, and when such permit has been granted a separate application need only be made in the case of a repair to any one engine, machine, or vehicle which would cost over £20 (twenty pounds).*

When boiler tubes are required, the exact number and specification must be given in each case.

It is advisable that owners should make application to the Agricultural Machinery Department at once for such priority certificates, and not wait until some repair is necessary.

Repairs to fixed machinery and plant are dealt with under a separate General Maintenance Permit, and application for this should be made direct by the owner of the plant, whether he be a farmer or an engineer, to the following address :—Ministry of Munitions, Priority Department, General Maintenance Section, 1, Caxton Street, S.W. 1.

THE following information (Ref. No. C.L. 194/L.3) was circulated by the Director of the Women's Branch of the Food Production Department of the Board in August :—

Money for Land Army Girls while Travelling. It has been brought to notice that members of the Land Army sent out from training centres, gang hostels, and depots to work in other counties frequently travel without any money. Even if arrangements have been made for them to be met, this constitutes a grave danger, as having no money of their own, they are liable to accept hospitality from strangers. To meet this difficulty it is suggested that :—

(1) *Training Centres*.—The second 4s. pocket money to which women are entitled for the last two weeks of their six weeks' training, should be given on the day they leave, in order that they may start with money in their pockets.

(2) *Gang Hostels*.—Women leaving gang hostels should be paid for their last week's work on the last day for the same reason.

(3) *Depots*.—The question of girls leaving depot is more difficult, but it is suggested that they should in every case be asked to deposit a small sum of money, say 2s., to be returned to them on leaving, or if a temporary day's work can be obtained for them they should be paid for this on the day they leave the depot.

THE following information was issued by the Food Production Department of the Board towards the end of August :—

In a fine autumn sunflower seed will ripen in the open, but care must be taken to protect it from birds and to prevent the ripe seed from falling on the ground. A small piece of muslin should be tied over each head, if the planting is small. When the head shrivels and the seeds are ripe, the plants should be cut at the ground level, standing them with their heads uppermost like shocks or sheaves of corn. When the heads are thoroughly dry, they should be cut off and the remaining seeds threshed out by standing each head on its side and hammering it with a mallet. If the weather is dull or wet the ripening should be hastened by cutting the plants at ground level as soon as the seeds are plump. They should then be stood shock-wise, if possible, under cover in an outside house, barn, or room. Later, when the heads shrivel, they should be cut and dried off in an oven and the heads placed in single layers on the shelves of the oven in the evening, leaving the door slightly open. They should be removed when the fire is made up in the morning and replaced in the evening. When the heads are dry, the seeds should be threshed out and stored in bags in a dry place.

On large plantations, birds should be scared away by any of the usual methods. When the seed is plump, the plants should be cut at ground level and stacked in shocks or sheaves with the heads uppermost. If the weather is fine the sheaves may be kept in the open; if wet, under cover in a well ventilated place. If a kiln or hop-oast is available, it may be used for finishing off the drying, but if the seeds are exposed to a high temperature they will be useless for next year's sowing.

THE following Notice was issued by the Food Production Department of the Board towards the end of August :—

Although the Food Production Department will not continue to supply ordinary seed potatoes next season it will assist growers to obtain seed of certain of the less common immune varieties, among others "Edzell Blue"—a first early variety immune from wart disease. The Department this year arranged for the growing in Scotland of a quantity of "Edzell Blue" to be reserved for growers in infected areas of England and Wales. The Department will not carry out the distribution itself, but will merely supply forms which can be obtained free on application (to 72, Victoria Street, S.W. 1); and growers desiring

the seed must fill up these forms and send them to the firm acting as agents for the Department. All arrangements must be made with this firm regarding delivery, terms of payment and other details. In the first instance, it is intended that the agents of the Department shall deal with the trade; and orders will not be accepted for less than two tons or more than four tons. The seed will be available to the public through the ordinary retail channels or co-operative societies who hold the necessary licence, and small growers should make a point of putting in their orders at once. There is a special reason for this in the case of a potato like "Edzell Blue," which will not stand pitting well and should normally be boxed in the autumn as soon as possible after lifting. Very few small gardeners or allotment men will be planting more than seven to fourteen pounds of this variety next Spring, and they should get their seed at the earliest possible moment and sprout it in a box or on the floor of a cool, frost-proof room. If they do not take this advice they may be disappointed of their supply because the percentage of loss on "Edzell Blue" in store or clamp is so high that neither the farmer nor the merchant will be prepared to carry a large stock through the winter.

THE Food Controller is advised by the Boards of Agriculture for England and Wales and Scotland that it is not desirable in the interests of food production that the price of seed potatoes of first early varieties should be controlled. The Food Controller, therefore, does not propose to prescribe maximum prices for such seed potatoes. (*National Food Journal*, 28th August, 1918.)

AN Order (No. 1044), dated 22nd August, 1918, has been made by the Food Controller to the effect that:—

The Potatoes (1918 Crop) (Restriction) Order, 1918. 1. Except under and in accordance with the terms of a licence granted by or under the authority of the Food Controller, a person shall not on or after 31st August, 1918, either on his own behalf or on behalf of any other person sell or buy or offer to sell or buy any potatoes of the 1918 crop grown in Great Britain otherwise than for delivery before the 1st November, 1918.

2. This Order shall not apply to potatoes of the first early varieties.

NOTE.—Applications for licences under the above Order should be addressed to the Secretary, Ministry of Food (Potato Section), 100, Cromwell Road, London, S.W.7.

AN Order (No. 979), dated the 2nd August, 1918, has been made by the Food Controller to the effect that:—

The Potatoes Order, 1918. 1. Except under and in accordance with the terms of a licence granted by the Food Controller a person shall not on or after the 8th August, 1918, until further notice either on his own behalf or on behalf of any other person, buy, sell, or deal in or offer to buy, sell, or deal in any potatoes of the variety "King Edward" of the 1918 crop grown in England or Wales.

2. A person shall not on or after the 8th August, 1918, sell or offer or expose for sale, or buy or offer to buy potatoes otherwise than by weight.

3. Clauses 1 and 2 of this Order shall not apply to sales of potatoes in the ground.

THE SCHEDULE.

Order Revoked.	Extent to which Revoked.	Date at which Revoked.
The Potatoes Order, 1917, as amended. (S.R. & O. Nos. 949 and 998 of 1917 and Nos. 445 and 639 of 1918.)	Part I except Clauses 1, 2, 4, 5 and 6. Part III, the whole. Part IV, the whole. The 1st and 2nd Schedules.	8th August, 1918.
The Seed Potatoes (1917 Crop) Order, 1917, as amended. (S.R. & O. Nos. 1155 of 1917 and 138 of 1918.)	The whole Order.	8th August, 1918.
The Potatoes (Distribution) Order, 1918. (S.R. & O. Nos. 94 and 204 of 1918.)	The whole Order.	2nd August, 1918.
The Potatoes (Distribution) Order, No. 2, 1918. (S.R. & O. No. 617 of 1918.)	The whole Order.	2nd August, 1918.

THE following Notice was issued by the Food Production Department of the Board on 30th August :—

Reports on Potato Spraying.

A large number of interesting reports have already been received by the Food Production Department as to the effects of spraying the potato crop. Generally, where spraying has been done once only the crop has been attacked with disease if adjoining crops were affected ; but where two or three sprayings had been given the results in the large majority of cases have been excellent.

A number of firms this year have been pushing vigorously the sale of various proprietary mixtures ; and from time to time the Department has been asked whether it can recommend one or other of these mixtures. Broadly, the experience of the present season so far endorses the wisdom of the official refusal to advise the use of any but the official mixture—Burgundy or Bordeaux. Several experimentalists with certain proprietary mixtures have written to the Department complaining of their ineffectiveness. Burgundy or Bordeaux mixture certainly appears to give a much larger measure of protection than any of the other mixtures with respect to which reports have so far been received. Dealing with one of the latter mixtures, a Pembrokehire report declares that, although it was applied by the local Council, it is "useless." From Hampshire it was reported that another mixture was easily washed off by rain, and that its efficacy compared badly with 1 per cent. Burgundy mixture used on adjoining plots. These are sample reports from a considerable budget. On the other hand where Burgundy or Bordeaux has been intelligently used the benefits are almost invariably very marked.

AN Order (No. 1,090), dated 31st August, 1918, has been made by the Food Controller to the effect that :—

The Grain (Prices) Order, 1918. 1. No wheat, rye, oats or barley harvested in the United Kingdom in the year 1918, or tailings, dressings or screenings of any such grain may be sold at prices exceeding the

maximum prices applicable according to the provisions of this Order.

2. (a) (i.) The maximum price applicable on any transaction shall, subject as hereinafter provided, be a price at the rate specified in the following table :—

Date of Sale of Grain Sold.	Wheat and Rye Rate per Qr. of 504 lb.	Barley Rate per Qr. of 448 lb.	Oats Rate per Qr. of 336 lb.
	s. d.	s. d.	s. d.
Where sale is made before the 1st October, 1918, the price shall not exceed	75 6	67 0	47 6
Where sale is made in the month of October, 1918, the price shall not exceed	75 6	67 0	48 0
Where sale is made in the month of November, 1918, the price shall not exceed	75 6	67 0	48 6
Where sale is made in the month of December, 1918, the price shall not exceed	75 6	67 0	49 0
Where sale is made in the month of January, 1919, the price shall not exceed	76 0	67 0	49 6
Where sale is made in the month of February, 1919, the price shall not exceed	76 0	67 0	50 0
Where sale is made in the month of March, 1919, the price shall not exceed	76 0	67 0	50 6
Where sale is made in the month of April, 1919, the price shall not exceed	76 6	67 0	51 0
Where sale is made in the month of May, 1919, the price shall not exceed	76 6	67 0	51 6
Where sale is made on or after the 1st June, 1919, the price shall not exceed	76 6	67 0	52 0

(ii.) Where any grain is carried without railway transport direct from producer's premises to mill or miller's store near such mill, or to factory or manufacturer's store near such factory, for the purpose of manufacture in such mill or factory, the rate specified in the foregoing table shall be increased by 1s. per quarter. For the purpose of this Sub-clause no mechanical processes of a kind referred to in Clause 7 of this Order (except the drying of barley by kiln-drying or other mechanical process) shall be deemed to be manufacture.

(b) The rate per quarter during any period according to Sub-clause (a) of this Clause, is hereinafter called "the standard rate."

3. Where oats suitable for the manufacture of oatmeal, rolled oats, flaked oats, oat-flour, or other oats products for human consumption are bought by an oatmeal miller, or other manufacturer,

specifically for the purpose of such manufacture, or by a recognised dealer buying for the purpose of filling a specific order given in writing by such a miller or such a manufacturer, the maximum price shall be ascertained by adding 3s. per qr. to the standard rate.

4. (a) In the case of wheat, rye and barley so damaged as to be unfit for use in the manufacture of human food and wheat, rye and barley tailings, dressings and screenings which are unfit for use in the manufacture of human food, the maximum price shall be ascertained by deducting 7s. per qr. from the standard rate.

(b) In the case of oats improperly cleaned or containing an undue quantity of soil, and in the case of oats tailings, dressings and screenings, the maximum price shall be ascertained by deducting 5s. per qr. from the standard rate.

5. On the occasion of the purchase of any of the grain mentioned from any person who is a recognised dealer in grain and who is not the producer of the grain sold, the maximum price shall be ascertained by adding 1s. per qr. to the price otherwise applicable according to the foregoing provisions of this Order; provided that where the total quantity of the kind of grain purchased by one buyer from one seller does not, in any period of seven consecutive days, including the day of sale exceed $7\frac{1}{2}$ qr., the maximum price in respect of each quarter so purchased shall be ascertained by adding 5s. per qr. to the price otherwise applicable according to the foregoing provisions of this Order, and where such total quantity does not in that period amount to half a quarter the maximum price in respect of such sales shall be ascertained by adding 9s. per qr. to the price otherwise applicable according to the foregoing provisions of this Order.

6. (a) The maximum prices under this Order are fixed on the basis of the following terms and conditions being applicable to the transaction :—

- (i.) Payment to be net cash within seven days of completion of delivery, and monies then unpaid thereafter to carry interest not exceeding the rate of 5 per cent. per annum or Bank Rate, whichever shall be the higher ;
- (ii.) The grain to be delivered by the producer free on rail or barge, or to mill or store in accordance with the usual custom of the district ;
- (iii.) Any freight, haulage, portorage and cartage incurred after delivery in accordance with sub-clause (ii.) of this Clause to be for buyer's account.
- (iv.) All sack hire up to and including the time of delivery to rail, barge, mill or store by the producer to be for the producer's account, and all charges for sacks subsequent thereto to be for the buyer's account.

(b) Where the grain is sold on terms and conditions other than the terms and conditions stated in the foregoing part of this Clause, a corresponding adjustment shall be made in the maximum price. In particular :—

- (i.) Where grain is delivered by the producer to a distance greater than the distance corresponding with the usual custom of the district, a sum at the rate of 9d. per ton per mile for the extra distance shall be added to the maximum price.
- (ii.) Where the grain is delivered by the producer at his premises a sum at the rate of 9d. per ton per mile for the distance corresponding with the usual custom of the district shall be deducted from the maximum price.

7. On the occasion of a sale of any home-grown grain which has been mechanically treated by gristing, crushing, bruising, kibbling, splitting or other kindred process, or which has been kiln dried or dried by other mechanical method, the maximum price shall be ascertained by adding to the price otherwise according to the foregoing provisions of this Order, the cost of such treatment not exceeding a usual and reasonable charge.

8. A person shall not sell or buy or offer to sell or buy any of the grain mentioned at a price exceeding the maximum price applicable under this Order, or in connection with a sale or disposition or proposed sale or disposition of any such grain enter or offer to enter into a fictitious or artificial transaction or make or demand any unreasonable charge.

9. None of the foregoing provisions of this Order shall apply to any grain suitable for seed and sold specifically for the purpose of seed, in compliance with the provisions of the Testing of Seeds Order, 1918.* No grain so sold shall be used for any other purpose, and the buyer of any grain so sold shall (except where he is buying the grain for use as seed by himself) hand to his seller at the time of sale, a declaration signed by him that he will re-sell the grain specifically as and for the purpose of seed.

10. A person shall not sell or offer to sell any wheat, rye, oats or barley whether imported or home-grown otherwise than by weight.

11. A person shall not torrefy or bleach any wheat, rye, oats or barley, whether imported or home-grown.

12. For the purpose of this Order :—

“Qr.” shall mean in relation to wheat and rye a weight of 504 lb., in relation to barley a weight of 448 lb., and in relation to oats a weight of 336 lb.

“Recognised dealer” shall mean a person who in the ordinary way of business deals in grain for the purpose of his livelihood.

“Unfit for use in the manufacture of human food” shall mean grain which is so damaged or so inferior in quality that any flour or meal which could be milled therefrom would be unfit for use in human food.

THE Food Controller has been in consultation with the Board of Agriculture and Fisheries regarding the 1918 Onion Crop. In view of high freights and restrictions in shipping, it

Arrangement for 1918

Onion Crop.

is extremely important that the home production of onions should be increased very largely and up to the fullest extent which the supply of seed will allow. In order that the grower may be ensured an adequate return for his crops, the Food Controller announces that, in the event of it becoming necessary to fix any maximum growers' prices for the British Onion Crop of 1918, those prices will not be less than those indicated in the following scale :—

For delivery on or before 30th October, f.o.r. or f.o.b.	£15 os. per ton.
For delivery between 1st November and 31st December, f.o.r. or f.o.b.	£16 10s. „
For delivery from 1st January to end of season f.o.r. or f.o.b.	£18 os. „

AN Order (No. 1,029), dated the 15th August, 1918, has been made by the Food Controller to the effect that :—

**The Cereals
(Restriction) Order,
1918.**

1. This Order shall apply to the following articles, namely, wheat, rye, barley, dredge corn, and to tailings, dressings and screenings of wheat, rye, barley and dredge corn.

2. (a) A person shall not on or after the 1st September, 1918, sell or offer to sell any article of a kind to which this Order applies to any person other than :—

(i.) A miller buying for the purposes of a controlled flour mill ; or

(ii.) A recognised dealer in grain ; or

(iii.) A person requiring and holding a licence granted by or under the authority of the Food Controller for the purpose of entitling him to use the article for a manufacturing business carried on by him ; or

(iv.) In the case of grain which is suitable for seed, a person buying grain specifically for the purpose of seed.

(b) This clause shall not apply to any article in respect of which it is proved that at the time of sale it was unfit for use in the manufacture of human food.

3. (a) A person shall not on or after 1st September, 1918, sell or offer to sell any article to which this Order applies which is unfit for use in the manufacture of human food in a quantity of 10 cwt. or less, unless a certificate has been granted by or under the authority of the Food Controller to the effect that such article is unfit for use in the manufacture of human food.

(b) Where any certificate is granted to any person in respect of any such article, conditions may be attached to such certificate relating to the keeping of records and making of returns by that person, as to the persons to whom such article may be sold ; and as to the use to which such article may be put.

It shall be the duty of all persons concerned to comply with such conditions.

4. (a) Notwithstanding any provisions contained in the Orders mentioned in the Schedule to this Order, a person shall not, on or after the 1st September, 1918, except under and in accordance with the terms of a licence in writing granted to him by or under the authority of the Food Controller :—

(i.) Use or permit to be used any tailings, dressings or screenings of wheat, rye, barley, or dredge corn for animal food or for the manufacture of animal food ; or

(ii.) Use or treat or permit to be used or treated any wheat, rye, barley, or dredge corn for any purpose other than the purpose permitted by the said Orders for sound articles of the like kind.

(b) Nothing in this clause shall apply to the use or treatment of any article by or on behalf of a person who has bought such article in a quantity of 10 cwt. or less, sold in accordance with Clause 3 of this Order.

(c) Any licence granted under this Order may be granted subject to such terms and conditions as the Food Controller shall think fit.

5. A person authorised by or under the authority of the Food Controller may :—

(a) Enter any premises on which he suspects any article to which this Order applies to be ; or

(b) Inspect and take samples of any such article ; or

(c) Demand from any person in possession of or having control of any such article production of any certificate or licence granted under this Order, or any document referred to in any such licence.

6. A person shall not :—

- (a) Knowingly make or connive at the making of any false statement in any application for any licence or certificate under this Order.
- (b) Forge or alter any licence or certificate or any term or condition therein, or authority or other document issued in connection with or for the purpose of this Order; or
- (c) Personate or falsely represent himself to be a person to whom such a licence, certificate, authority, or other document has been issued or applies.
- (d) Obtain or attempt to obtain any licence or certificate upon any false application or upon any application containing any false statement in material particular, or upon any application where he has reason to believe that any statement in such application is false in any material particular.

7. For the purpose of this Order—

The expression "Recognised Dealer" shall mean a person who in the ordinary way of his business deals in grain for the purpose of his livelihood.

The expression "unfit for use in the manufacture of human food," in connection with any article to which this Order applies, shall mean so damaged or so inferior in quality that any flour or meal which could be milled from such article would be unfit for use in human food.

8. Infringements of this Order are summary offences against the Defence of the Realm Regulations.

The Schedule.

The Wheat, Rye and Rice (Restriction) Order, 1917.*

The Barley (Restriction) Order, 1917.†

The Dredge Corn Order, 1917.‡

IN Leaflet No. 10, issued by the Joint Committee of the Board of Agriculture and the Ministry of Food, it is stated that the Order published above has been made because it is urgently necessary to save for human consumption all grain of this kind that is fit for the purpose and so to release ships for the transport of men and munitions.

**Leaflet on The
Cereals (Restriction)
Order, 1918.**

The leaflet is meant to explain to growers of grain, and to persons wishing to feed grain to animals, how the Order chiefly affects them.

Grain fit for Human Consumption.—Grain of the kinds described above, if fit for human consumption, may not be fed to animals, and may be sold only to :—

- (i.) A miller buying for the purpose of a controlled flour mill.
- (ii.) A recognised dealer in grain.
- (iii.) A person requiring or holding a licence for the purpose of manufacture.
- (iv.) In the case of grain suitable for seed, a person buying such grain for the purpose of seed.

In selling grain for seed under this Order farmers and others must comply with the Testing of Seeds Order, 1918, and any other Order affecting the sale of seeds.

* Order No. 376, 1917, printed in this *Journal*, May, 1917, p. 236.

† Order No. 821, 1917, printed in this *Journal*, September, 1917, p. 683.

‡ Order No. 1182, 1917, printed in this *Journal*, December, 1917, p. 1028.

Grain unfit for Human Consumption.—The Order forbids the feeding of grain of the kinds described above to any animal, unless a licence has been obtained. Exception is made in the case of persons buying unfit grain for this purpose in lots of 10 cwt. or less. In such cases the person selling the grain is responsible for getting a certificate of its unfitness before he sells it.

How to get a Certificate or Licence for Unfit Grain.—A farmer or other person wanting to sell grain that is unfit for human consumption in quantities of 10 cwt. or less should obtain a form of application (Form G. 1.) for a certificate from :—

- (i.) The Local Food Office ; or
- (ii.) The Grain Officer at the Corn Exchange, or Grain Market, on recognised market days ; or
- (iii.) The Divisional Food Commissioner, or a Grain Officer authorised by him.

These forms can be obtained (and returned) personally or through the post.

Persons proposing to sell grain that is unfit for human consumption in quantities exceeding 10 cwt. need not obtain a certificate.

Farmers or other persons wanting to feed grain that is unfit for human consumption to animals (except when they have bought such grain in a lot of 10 cwt. or less) must obtain in the same way a form of application (Form G. 2.) for a licence.

Every application must be accompanied by a sample of the grain in question. Each sample must be in an ordinary unglazed sample bag with the name and address of the applicant, the quantity and description of the bulk to which the sample relates, and the date of the application clearly written either on the bag itself or on a label securely attached to it. The Ministry of Food is obtaining a supply of bags for this purpose, and these will be issued to Grain Officers as soon as they are delivered by the manufacturers. As a further safeguard a slip of paper containing applicant's name and details of the grain should, if possible, be enclosed inside the bag with the grain.

The Food Controller trusts that farmers will recognise that this Order is made in view of a grave national need, and that they will assist him by loyally observing its provisions. In securing its observance he desires to cause as little inconvenience to farmers as possible. He is making, through the Divisional Food Commissioners, arrangements for the prompt grant of certificates and licences. If in any district farmers experience difficulty in getting their applications dealt with, they are asked to write and tell their Food Commissioner.

NOTE.—Copies of the leaflet may be obtained free of charge and post free on application to :—*The Secretary, Joint Committee of the Board of Agriculture and Ministry of Food, 6a, Dean's Yard, Westminster, S.W. 1,* and envelopes so addressed need not be stamped.

THE following Order, dated 30th July, 1918, has been issued by the Army Council under the Defence of the Realm Regulations :—

**Prohibition of the
Lifting and Use of
Hay and Straw in
England and Wales.**

In pursuance of the powers conferred on them by the Defence of the Realm Regulations and of all other powers thereunto enabling them the Army Council hereby give notice that all hay and threshed hay, oat straw and wheat straw, rye wheat straw,

buckwheat straw, barley straw, mustard straw, rye straw, pea straw, bean straw and threshed tares (hereinafter in this Order referred to as hay and straw forage) now standing in bulk in England and Wales or as and when harvested, except such hay or straw of the 1917 or earlier crop as has been released by sale licence, is taken possession of by the Army Council and shall from the date of this Order, or as and when harvested, be held at the disposal of the duly authorised officers of the War Department.

2. Producers and consumers having hay and straw forage in their possession at the date of this Order may continue (subject as regards producers to the provisions of paragraph 3 hereof) to use a reasonable quantity of such hay and straw forage for consumption by stock in their possession or under their control.

3. Every producer desirous of using hay and straw forage in his possession for consumption by stock in his possession or under his control must forthwith make application in writing to the District Purchasing Officer for Supplies of the county in which the hay and straw forage is situate for such hay and straw forage to be inspected with a request that a producer-consumer's licence may be issued to him for such quantity thereof as he may require for consumption by stock in his possession or under his control for the period ending the 30th September, 1919. Such application must state (a) the description and estimated quantity of hay and straw forage in the applicant's possession, and if it is standing in ricks or bays the number of such ricks or bays and the approximate tonnage of each, (b) the description of hay and straw forage and the estimated quantity of each description he will require for consumption by stock in his possession or under his control, (c) the number and description of stock in his possession or under his control.

4. Until inspection has been made and the application for a producer-consumer's licence has been finally disposed of the producer may continue to use a reasonable amount of hay and straw forage in his possession for consumption by stock in his possession or under his control.

5. Any producer-consumer's licence shall be liable to revision on and after the 15th April, 1919.

6. All hay and straw forage in the possession of the producer for which a producer-consumer's licence has not been issued as aforesaid will be taken by the Army Council.

7. (a) Should any producer consider that the quantity of hay and straw forage allowed by any producer-consumer's licence for his own consumption is insufficient for his needs he may appeal by a written notice within 14 days of the issue of such licence to the Farm Produce County Committee of the county in which the hay and straw forage is situate whose decision shall be final, or (b) should any producer consider in the case of hay and straw forage in respect of which the price offered to him is less than any fixed price above which the sale thereof is prohibited by virtue of the Defence of the Realm Regulations or any Order made thereunder that the price offered to him is inadequate he may either (i.) appeal by written notice within 14 days of such price being offered to the Farm Produce County Committee of the county in which the hay and straw forage is situate whose decision shall be final, or (ii.) obtain the decision (in default of agreement) of the tribunal by which claims for compensation under the Defence of

the Realm Regulations are in the absence of any express provision to the contrary determined in accordance with the provisions of Regulations 2B of the said Regulations.

8. All hay and straw forage taken by the Army Council will be taken upon the terms of a Purchase Note to be signed by the producer, and where such Purchase Note is signed by the producer at the time of taking, interest at certain rates as set out in the Purchase Note will be added to the price stated thereon. In the event of a producer refusing or neglecting to sign such Purchase Note such interest will not be payable, except that where a producer has appealed to the Farm Produce County Committee as provided in paragraph 7 (b) of this Order and the Farm Produce County Committee has upheld his appeal, he shall receive interest as aforesaid as though the appeal had not been made or the signature had not been withheld.

9. No person may deal in hay and straw forage without a licence. Application for such licences must be made to the Civil Supplies Central Control Council through the County Distributing (Forage) Committee.

10. All consumers (other than producers) must register with one or more dealers or producer-distributors, and when applying to register with any dealer or producer-distributor must state (a) the number of animals for which hay and straw forage is required, (b) the classification of such animals, (c) the description and quantity of each description of hay and straw forage required, and (d) the place at which it is required.

Should the number of animals in the consumer's possession increase or decrease after registration such increase or decrease must be notified by him to the dealer or producer-distributor concerned.

11. All persons requiring straw for thatching (except in the case of a producer), packing, paper manufacturing or any other purpose whatsoever other than consumption by animals must make application to the County Distributing (Forage) Committee of the county concerned, stating (a) the description and quantity of straw required, (b) the purposes for which it is required, (c) the place at which it is required, and (d) the name and address of the person from whom it is desired to obtain supply.

12. All licences issued under this Order will be issued subject to the conditions and restrictions contained in such licences. Any departure from such conditions and restrictions or other act in contravention of the provisions of this Order will be an offence under the Defence of the Realm Regulations, and will render the offender liable to the penalties attaching thereto.

13. Detailed instructions regarding the necessary procedure to be adopted by all persons desiring to use, sell, purchase or otherwise deal in hay and straw forage under this Order can be obtained upon application to the Secretary of the Forage Committee, 64, Whitehall Court, S.W. 1.

14. The addresses of the District Purchasing Officers for Supplies, mentioned in paragraph 3 are as under :—

18. So much of the Army Council Order of the 17th July, 1917, prohibiting the lifting of hay and straw in Great Britain and Ireland and the Isle of Man as relates to the lifting of hay and straw in England and Wales is hereby cancelled, but nothing in this Order shall affect the said Order of the 17th July, 1917, in so far as it relates to the lifting of hay, oat and wheat straw in Scotland, Ireland and the Isle of Man.

AN Order (No. 1,028), dated the 16th August, 1918, has been made by the Food Controller and contains the following main provisions:—

1. (a) A person shall not sell or offer or expose for sale or buy or offer to buy any wild rabbits or any part thereof at a price exceeding the maximum price for the time

being applicable under this Order.

(b) Until further notice the maximum price for wild rabbits shall be at the rate applicable according to the Schedule and the subsequent provisions of this Order.

(c) The Food Controller may at any time by notice under this Order prescribe other prices for wild rabbits.

2. On the occasion of a sale (other than a sale by retail) of any wild rabbits the maximum price shall be:—

(i.) On a sale to a collector buying in the ordinary course of his business at the rate applicable according to Part 1 of the Schedule.

(ii.) On any other sale at the rate applicable according to Part 2 of the Schedule.

3. The maximum price applicable under Clause 2 (ii.) is fixed on the basis of the following terms and conditions being applicable to the transaction:—
